# INDEX

- Aarkrog, A., and Lippert, J.: Comparison of Relative Radionuclide Ratios in Debris from the Third and the Fifth Chinese Nuclear Test Explosions, 1001
- Ability: Genetic and Environmental Factors in Human (edited by J. E. Meade and A. S. Parkes), Symposium 1965, review by A. T. Welford, 972
- Abortion Law, news, 223
- ABO System and the Metabolism of Human Spermatozoa: Antibodies of the (D. R. Ackerman), 253-6
- Abraham, M. H.: Carbanions in Synthesis, review, 237
- Abramoff, Peter, and Thomson, R. G.: Experimental Approach to Biology, review by A. K. Thomas, 1181
- Abramow, M., and Corvilain, J.: Effect of Growth Hormone on Tubular Reabsorption of Glucose and Phosphate, 85
- Abrikosov, A. A., Gor'kov, L. P., and Dzyaloshinskii, I. Ye.: Quantum Field Theoretical Methods in Statistical Physics, Second Edition, review by S. F. Edwards, 128
- Absolute Magnitudes of Quasistellar Radio Sources (G. C. McVittie and R. Stabell), 133-5
- Absorption Bands associated with the Hydrogen Bondings of Thymine and Uracil: Electronic (J. Tanaka and M. Tanaka), 68-70
- Absorption of Exogenous and Endogenous Biliary Copper in the Rat (P. Farrer and S. P. Mistilis), 291
- Absorption of Microwaves in Human Tissues: Dielectric (J. R. Mallard and D. G. Lawn), 28-30
- Abstracts: Collaboration on, 433
- Acetabularia mediterranea: Protein Synthesis in the Absence of the Nucleus (J. Brachet), 650-5
- Acetate as a Precursor for Metabolic Investigations in Insects: Topically Applied *n*-Decyl (J. P. Heslop), 291
- Acetate Repression of Chlorophyll Synthesis in *Euglena gracilis* (D. E. Buetow), 1127
- Acetoacetate Condensate: Glucosamine, a New Anti-Alloxan Diabetes Factor (J. L. Padron et al.), 1254
- bis-(Acetylacetonato) Zinc: A New Type of bis-(Acetylacetonato) metal (II) Polymer: the Trimer of (M. J. Bennett et al.), 174
- Acetylation on the Biological Activity of Pregnant Mare Serum Gonadotrophin: Effect of (G. C. Becking and J. F. Hayden), 1029
- Acetylcholine Induced Contraction of Skeletal Muscle by Sea Snake Venom: Antagonism of Intra-arterial (K. E. Chan and S. L. Geh), 1147
- Acetylcholine by Strychnine and its Implications regarding Transmission by the Olivo-cochlear Bundle: Inhibition of Release of (D. N. McKinstry and G. B. Koelle), 505
- Acetylcholine: Two Different Excitatory Transmitters acting on a Single Molluscan Neurone (H. M. Gerschenfeld et al.), 359
- Acetylcholinesterase by Antibodies to the Native Enzyme: Restoration of Enzyme Activity of Heat-denatured (D. Michaeli et al.), 77
- Acetylene-Oxygen Flames: Formation of Polycyclic Aromatic Hydrocarbons in Premixed (R. Long and E. E. Tompkins), 1011
- Acid hydrolases: Dual Localization of  $\beta$ -Glucuronidase in Endoplasmic Reticulum and in Lysosomes (W. H. Fishman et al.), 457-60
- Acid Mucopolysaccharides (AMP): Disk Electrophoresis of (O. M. Rennert), 1133
- Urinary Excretion Patterns of Individual (W. M. Teller), 1132
- Ackerman, D. R.: Antibodies of the ABO System and the Metabolism of Human Spermatozoa, 253-6
- Acoustical Society: Council of the British, Officers, 8
- Acoustics: Ocean (I. Tolstoy and C. S. Clay), review by A. O. Williams, jun., 1181
- ACTH and FSH on the Adrenal Cortex in Hypophysectomized-Gonadectomized Rats: Possible Synergic Influence of (H. Mikolajczyk), 806
- Actin Filaments: Axial Period of, Electron Microscope Studies (J. Hanson), 353-6, X-Ray Diffraction Studies (B. M. Millman et al.), 356-8
- Action Potential Phenomena in Experimental Bimolecular Lipid Membranes (P. Mueller and D. O. Rudin), 603
- Action Potential of the Squid Giant Axon: Dependence on Temperature of the Conduction Velocity of the (R. A. Chapman), 1143
- N-Acyl Derivatives: *In vitro* Anticholinesterase Activity of Certain N-Methylcarbamate Insecticides compared with their (D. K. Lewis), 205
- Adams, C. W. M.: Chemistry and Physics of Lipids, Vol. 1, No. 1, 1966/67, review, 974
- Adaptation and Growth Characteristics of Influenza Virus at 25°C (H. F. Maassab), 612-4
- Adaptation and Partial Dormancy in *Ascaris* Eggs: Physiological (P. A. G. Wilson), 715-7
- Adelman, S. L., Brewer, A. K., Hoerman, K. C., and Sanborn, W.: Differential Identification of Micro-organisms by Analysis of Phosphorescent Decay, 718-20
- Adenosine Diphosphate: Membrane Active Drugs and the Aggregation of Human Blood Platelets (D. C. B. Mills and G. C. K. Roberts), 35-8
- ATPases in the Sarcoplasmic Reticulum of Skeletal Muscle Fibres: Two (F. Giacomelli, C. Bibbiani, E. Bergamini and C. Pellegrino), 679-82
- Adenosine Triphosphate and the Biosynthesis of Porphyrins in the Livers of Rats intoxicated with 'Sedormid': Correlation between the Concentration of (A. Gajdos, M. Gajdos-Török, A. Palma-Carlos and L. Palma-Carlos), 1022
- ATP Synthesis: Chemiosmotic Hypothesis of Oxidative Phosphorylation (P. Mitchell and J. Moyle), 139-9
- Adenovirus Type 12: *In vitro* Transformation of Cells of Hamster Brain by (I. Yamane and T. Kusano), 187
- Wasting Syndrome in Thymectomized Immature Baboons (*Papio* Species) after Infection with (S. S. Kalter et al.), 610-12
- Adenovirus 12 Tumour Cells in Hamsters immunized with Various Adenoviruses: Inhibition of Tumour Formation with (G. C. Schild), 519
- Adgie, R. L., et al.: Measurements of OH Emission Sources with an Interferometer of High Resolution, 1109
- Radio Diameter Measurements with Interferometer Baselines of One Million and Two Million Wavelengths, 789
- Adhesiveness: Effect of Prolonged Exercise on Platelet (G. D. Pegrum et al.), 301
- Adjuvant Principle of Pertussis Vaccine for the Mouse: Further Studies on the (R. E. Pieroni and L. Levine), 1015-7
- Adrenal Cortex in Hypophysectomized-Gonadectomized Rats: Possible Synergic Influence of ACTH and FSH on the (H. Mikolajczyk), 806
- Adrenal Cortical Control of the Appearance of Rat Slow Alpha<sub>2</sub>-Globulin (W. G. Heim and S. R. Ellenson), 1260
- Adrenalectomy on *in vitro* Aminoacid Incorporation into Microsomes of P1798 Lymphosarcoma: Effects of Corticoid Injection and of (V. P. Hollander et al.), 1036
- Adrenal Glands in Rats during Long Term Administration of Histamine: Shock-like Symptoms and Hyperplasia of the (H. Mikolajczyk), 805
- Adrenal Glands of Wild Rabbits: Morphological Changes in the (K. Myers), 147-50
- Adrenaline by a New Histochemical Technique: Demonstration of Nerve Terminals containing (E. T. Angelakos and M. P. King), 391
- Adrenaline on the Rat Uterus: Motor Effect of (A. Tothill), 1230
- Adrenals: Effect of Feeding Calcium Cyclamate to Rats (P. O. Nees and P. H. Derse), 1191-5
- A-Adrenergic Blocking Agent: Enhancement of the Post-irradiation Protective Action of TAB by an (J. W. Byron), 635
- $\beta$ -Adrenergic Receptor Blocking Agent: Metabolism of Propranolol ('Inderal'), a Potent, Specific (P. A. Bond), 721
- Adrenergic Blocking Agents: Inhibition of the Extraneuronal Metabolism of Noradrenaline in the Isolated Heart by (A. J. Eisenfeld et al.), 297
- Adsorption of the Three Hydrogen Isotopes on Charcoal (P. M. S. Jones and C. G. Hutcheson), 490
- Aedes aegypti* Linn.: Aseptic Rearing of (J. Boorman), 197
- Aedes aegypti* L. on a Dry Surface and Hygroreceptors: Oviposition of (M. Bar-Zeev), 737
- Aeneolamia varia saccharina* (Distant) Artificial Diet for the Adult Frog hopper (E. A. C. Hagley), 414
- Aerodynamics: see Swinging Wings, news, 6
- Aeroplane (1799-1909): Invention of the (C. H. Gibbs-Smith), review by J. T. Henshaw, 763
- Aerosols: Death of *Saccharomyces cerevisiae* in (J. D. Chapman et al.), 465-8
- Aetiological Significance of Rod-shaped Bodies in Rheumatoid Synovia (S. Roy and F. N. Ghadially), 1139
- Afar depression: Major Volcano-Tectonic Lineament in the Ethiopian Rift System (P. A. Mohr), 664
- Afferents and Motor Control: Muscular (edited by R. Granit), Nobel Symposium 1965, review by W. F. Floyd, 445
- Aflatoxin, news, 543
- African Academy: East, news, 435
- African Cucurbit, *Ruthalicia*: Peculiar Placenta in (H. L. Chakravarty), 313
- Agar Cultures by Proliferation of Mouse Bone Marrow Cells: Stimulation by Leukaemic Sera of Colony Formation in Solid (T. R. Bradley et al.), 926
- Ageing Eggs of the Rabbit: Chromosome Deterioration in (C. R. Austin), 1018
- Ageing and the Fidelity of Protein Synthesis in *Drosophila* (B. J. Harrison and R. Holliday), 990-2
- Agglutinin by 2-Mercapto-ethanol: Reversible Inactivation of *Helix* (pomatia) (G. Uhlenbruck et al.), 76
- Aggregation of Human Blood Platelets: Membrane Active Drugs and the (D. C. B. Mills and G. C. K. Roberts), 35-8
- Agriculture: at British Universities, 219, news, 221, at the University of Nottingham, news, 434
- Agrobacterium tumefaciens* on Pinto Bean Leaves: Time required for Tumour Initiation by (J. A. Lippincott and B. Lippincott), 596-8
- Aguilera, A., Colombara, E., Pieber-Perreta, M., and Tohá, C. J.: Increased Radiosensitivity in *Lens esculentum* Seeds irradiated in a Mononucleotide Solution, 176-8
- Ahmad, M. U.: Some Geophysical Observations on the Great Glen Fault, 275-7
- Aid Distribution, news, 4
- Airborne Diameters of Respiratory Droplets and the Diameter of the Stains left after Recovery: Relation between (R. G. Loudon and R. M. Roberts), 95
- Aircraft: Supersonic, One Basket for Eggs, I, Supersonic Contract, 5, Swinging Wings, 6
- Air-entraining Water Flows: Aspects of Similarity for (M. J. Kenn and K. J. Zanker), 59
- Air Flow with Arc Present (L. H. A. King and M. K. Ancilewski), 586
- Airglow: Balloon-borne Observations of Brightness Variations in the (0,0) Band of the ( $\Delta\alpha-\Sigma\alpha$ ) System of Oxygen in the Day and Twilight (W. F. J. Evans et al.), 352
- Air Masses, Movement of: Radioactive Ruthenium and Manganese Isotopes in the Atmosphere (M. N. Rao and K. R. Menon), 26
- Air: Technique for Detecting Lead Particles in (G. M. Morgan, jun.), 58
- Air Tide: Lunar (B. Haurwitz and S. Chapman), 9-13
- Airy Shaw, H. K. (revised by): Dictionary of the Flowering Plants and Ferns (J. C. Willis), Seventh Edition, review by M. Lindley, 555
- Aisenberg, Alan C., and Wilkes, B.: Immunological Tolerance induced by Cyclophosphamide assayed by Plaque Spleen Cell Method, 498
- Akoyunoglou, G., and Argyroudi-Akoyunoglou, J. H.: Mechanism of Action of Carboxydismutase, 287
- Aksoy, Muzaffer, and Erdem, S.: Decrease in the Concentration of Haemoglobin A<sub>2</sub> during Erythroleukaemia, 522
- Aladjem, F., et al.: Radioimmunoassay of Bradykinin, 1130
- Albatrosses *Diomedea melanophris* and *D. chrysostoma*: Breeding Frequency in the (W. L. N. Tickell and R. Pinder), 315
- Albritton, E.: Information Exchange Groups, Correspondence, 1065
- Alburn, Harvey E., and Fenichel, R. L.: Hyperglycaemia induced by Insulin B Chain in Dietary Diabetes in Rats, 515
- Alcohol in Albino Rats: Effect of Two Diuretic Drugs on Liquid Consumption and Free Choice of (K. Eriksson), 316

- Alcohol Dehydrogenase by Chloroquine: Inhibition of (R. Fiddick and H. Heath), 628
- Alcoholism (M. Hayman), review by D. L. Davies, 1179
- Aldabra, news, 854
- Aldabra Atoll: Ecology of (D. R. Stoddart and C. A. Wright), 1174-7
- Aleksandrov, Igor Vladimirovich: Theory of Nuclear Magnetic Resonance, review by J. G. Powles, 18
- Alexander, P., Delorme, E. J., Hamilton, L. D. G., and Hall, J. G.: Effect of Nucleic Acids from Immune Lymphocytes on Rat Sarcomata, 569-72
- Alexander, R. McN., and Yazdani, G. M.: Respiratory Currents of Flatfish, 96
- Alexander, Dr. W. O.: Appointment as Professor and Head of the Department of Metallurgy in the University of Aston in Birmingham, 118
- Alfalfa: Seasonal Variation in the Concentration of Caesium-137 in Grass and (S. Csupka et al.), 1204-6
- Algae: Proteins in the Cell Walls of Some Green (E. W. Thompson and R. D. Preston), 684
- Simple Device for obtaining Synchronous Cultures of (A. Lafeber and C. L. M. Steenbergen), 527
- Algal Growth-promoting Substances on Growth, Yield and Protein Contents of Rice Plants: Influence of (A. C. Shukla and A. B. Gupta), 744
- Algorithms: Introduction to Cybernetics (V. M. Glushkov), review by J. D. Cowan, 237
- Aliphatic Hydrocarbons in Metasediments (J. Oró and D. W. Nooner), 1085-7
- Aliphatic Hydrocarbons in Pre-Cambrian Rocks (J. Oró and D. W. Nooner), 1082-5
- Alkaloids among Strains of *Phalaris tuberosa* L.: Variation in Concentration and Composition of Toxic (R. N. Oram and J. D. Williams), 946
- Alkane-Nitrous Oxide Mixtures: Role of O- in the Gas Phase Radiolysis of (J. M. Warman), 381
- Alkanes: Aliphatic Hydrocarbons in Pre-Cambrian Rocks (J. Oró and D. W. Nooner), 1082-5
- Allele at the Phenylalanine Hydroxylase Locus in Man: Third (L. I. Woolf et al.), 883
- Alleles of Cocoa: Incompatibility (D. R. Glendinning), 306
- Allelism of the S Gene: Combinations of Peroxidase Isozymes determine Multiple (K. K. Pandey), 669-72
- Allen, K. W.: *Obituary of Dr. Paul White*, 448
- Allergy in Infant Germ-free Rabbits: Milk (M. E. Coates and P. N. O'Donoghue), 307
- Allnatt, A. R., Chadwick, A. V., and Pantelis, P.: Voltages produced by Oxygen in Platinum-Sodium Chloride Crystal Cells, 1226
- Allografts on the Oestrous Cycle of the Syrian Hamster: Influence of Multiple Anterior Pituitary (J. W. McDaniel et al.), 195
- Allografts and Xenografts of Oviduct to the Cheek Pouch of the Syrian Hamster (J. W. McDaniel and D. L. Black), 710
- Alloy Films: Methods for interpreting Electron Diffraction Patterns of Thin (J. A. Bicknell and H. Lipson), 169
- Alloys: Extension of the Sub-regular Solution Model for Binary (J. S. Llewellyn Leach), 587
- Formation of, at Room Temperature (H. Hirsch), 793
- Allyl and  $\beta$ -Methylallyl Free Radicals in the Far Ultra-violet: Electronic Spectra of the (A. B. Callear and H. K. Lee), 693
- Alper, Paul: Theory of Automatic Control, review, 447
- Alphabet: Initial Teaching, news, 433
- Alpha<sub>2</sub>-Globulin: Adrenal Cortical Control of the Appearance of Rat Slow (W. G. Heim and S. R. Ellenson), 1260
- $\alpha$ -Glucose-1-phosphate: Hypothesis on the Mode of Conversion of Glucose into (E. E. Smith et al.), 733
- $\alpha$ -Keratin: X-ray Evidence of Regularly Distributed Lysine in (G. Heidemann and H. Halboth), 71
- $\alpha$ -Receptors: Depressor Effects with Sympathomimetic Amines after Blockade of Cardiovascular (B. Blackwell and E. Marley), 840
- Alpha-Tocopherol and Erythrocyte Structure in Rats: Dietary Retinol and (O. R. Anderson et al.), 47-9
- Altithermal Timberline Advance in Western United States (V. C. Lamarche, jun., and H. A. Mooney), 980-2
- Altman, K. I., and Gerber, G. B.: Catabolism of Tryptophan by the Isolated, Perfused Liver and Intestine, 911-3
- Altman, Philip L., and Dittmer, D. S. (compiled and edited by): *Environmental Biology, Handbook*, review by J. Ernstring, 1180
- Altstein, A. D., Vassiljeva, N. N., and Sarycheva, O. F.: Neoplastic Transformation of Rat Embryo Cells by Simian Papovavirus SV<sub>40</sub>, 931
- Alumina: Separation and Analysis of some *cis, trans* Isomeric Olefines on Activated (G. R. List et al.), 380
- American Institute of Physics: Officers, 437, news, 750
- Amides: Structure and Activity in Molluscs (J. P. de Villiers and M. M. Roussouw), 1208
- Amine Synthesis in Barley: Relation between Mineral Deficiency and (C. Sinclair), 214
- Amines after Blockade of Cardiovascular  $\alpha$ -Receptors: Depressor Effects with Sympathomimetic (B. Blackwell and E. Marley), 840
- Amino-acid: Metabolic Pathways of Red Blood Cell Copper in Normal Humans and in Wilson's Disease (P. Z. Neumann and M. Silverberg), 775-9
- UGA: A Third Nonsense Triplet in the Genetic Code (S. Brenner et al.), 449
- Amino-acid analogues: Senescence and the Fidelity of Protein Synthesis in *Drosophila* (B. J. Harrison and R. Holliday), 990-2
- Amino-acid Composition of  $\alpha_2$ -Casein D (P. J. de Koning and P. J. van Rooijen), 1028
- Amino-acid Composition of Ascitic Fluid and Blood Plasma from Mice bearing Ehrlich-Lettre Tumour (P. A. Dreyes and R. W. McKee), 411
- Amino-acid Incorporation: Inhibitory Effect of Salicylates and Cinchophen Derivatives on (M. Reunanen et al.), 918
- Amino-acid Incorporation into Microsomes of P1798 Lymphosarcoma: Effects of Corticoid Injection and of Adrenalectomy on *in vitro* (V. P. Hollander et al.), 1036
- Amino-acid Replacements in Horse Haemoglobin (J. V. Kilmarin and J. B. Clegg), 269-71
- Amino-acids: Aromatic and Subaromatic containing, Action of Atomic Hydrogen on Ribonuclease in Aqueous Solution (B. E. Holmes et al.), 1087-91
- In Recent Sediments off South-east Devon, England (R. H. Clarke), 1003-5
- Effect of, on the Transport of Bovine Immune Lactoglobulin across Newborn Pig Intestine (M. W. Smith and A. E. Pierce), 1150
- 2- $\beta$ -Amino ethyl isothiourea (AET) given at Various Intervals before Irradiation: Protective Effect of Cystamine and (L. Tkadlecěk and V. Jurašková), 1267
- Aminopeptidase A Activity: Relationship between Parathyroid Function and Serum (I. Nagatsu and J. Hara), 206
- Aminopeptidase Activity in Early Wound Healing: Biochemical and Histochemical Observations on (J. Raekallio and P.-L. Mäkinen), 1037
- 1-Amino-4-phenyl Pyridinium Chloride: a Potential Antihypertensive Agent (R. T. Brittain, J. B. Farmer, D. Jack, J. E. Martin and A. C. Ritchie), 731
- $\delta$ -Aminosuccinyl Ornithine in Cell Wall Hydrolysates of *Lactobacillus cellobiosus*: Identification of L-Ornithine and (R. Plapp and O. Kandler), 803
- Aminothiol Radioprotectors: Mechanism of Action of (P. E. Brown), 363
- Ammonia-Hydrogen Chloride System: Effect of Moisture on Liesegang Ring Formation in (G. A. Davies et al.), 279
- Amnion Cells: Growth Regulatory Effects of Cellular Interaction (H. Eagle and E. M. Levine), 1102-6
- Amoebal Ribosomes: Protein Synthesis by (W. A. Carter et al.), 722-4
- Amorphous Nucleation in Metals (C. W. B. Grigson), 277-9
- Amphibian Eggs: Protein Synthesis in the Absence of the Nucleus (J. Brachet), 650-5
- Amphidiploid Species of *Brassica*: *B. amarifolia* Narain and Prakash: Synthesis of a New (A. Narain and S. Prakash), 198
- Amygdalectomy in the Maternally Reared and Maternally Deprived Macaque: Effects of Neonatal (A. Kling and P. C. Green), 742
- Amyloidosis by Cadmium: Induction of (J. Baum and H. G. Worthen), 1040
- Anaerobic Glycolysis: Antibodies of the ABO System and the Metabolism of Human Spermatozoa (D. R. Ackerman), 253-6
- Anaesthesia, Vol. 2: Animal (M. Westhues and R. Fritsch), review by B. M. Q. Weaver, 235
- Anaesthesia: Electrolyte Imbalance as the Mechanism for Inert Gas Narcosis and (P. B. Bennett and A. J. Hayward), 938
- Analysis: Fundamentals of Mathematical (G. M. Fikhtengol'ts) Two Volumes, review by R. L. Perry, 131
- Modern Methods of Chemical (J. A. Barnard and R. Chayen), review by J. K. Foreman, 554
- Analysis of Phosphorescent Decay: Differential Identification of Microorganisms by (S. L. Adelman et al.), 718-20
- Analysis of Series of Events: Statistical (D. R. Cox and P. A. W. Lewis), review by W. A. O'N. Waugh, 656
- Analytical Chemistry, Vol. 4 (edited by C. E. Crouthamel, D. C. Stewart and H. A. Elion), *Progress in Nuclear Energy, Series 9*, review by A. A. Smales, 659
- Analytical Chemistry: Treatise on (edited by I. M. Kolthoff and P. J. Elving), Part 1: Vol. 6, review by J. K. Foreman, 17
- Anaphylactic Antibody in Rats infected with *Nippostrongylus brasiliensis*: Thymectomy and (R. J. M. Wilson et al.), 398
- Anaphylaxis: Release of Catecholamines in the Guinea-pig by Substances involved in (P. J. Piper et al.), 838-40
- Ancilewski, M. K., and King, L. H. A.: Air Flow with Arc Present, 586
- Andriolová, A., and Ruttkay-Nedecký, G.: Polarography of Proteins containing Cysteine, 564
- Anderson, B., et al.: Radio Diameter Measurements with Interferometer Baselines of One Million and Two Million Wavelengths, 789
- Anderson, J. A., Feldman, A., and Williams, M. M. D.: Early Fading of Thermoluminescence induced by Radiation in Lithium Fluoride, 61
- Anderson, N. F., and James, K.: Effect of Anti-rat Lymphocyte Antibody on Humoral Antibody Formation, 1195-7
- Anderson, O. Roger, Roels, O. A., and Pfister, R. M.: Dietary Retinol and Alpha-Tocopherol and Erythrocyte Structure in Rats, 47-9
- Anderson, Dr. P. W.: Appointment as Visiting Professor in Theoretical Physics in the University of Cambridge, 858
- Anderson, T. B.: Kink-bands and Related Geological Structures, 54
- Andrew, R. J.: Intracranial Self-stimulation in the Chick, 847
- Andrews, Gould A., Kniseley, R. M., and Wagner, jun., H. N. (edited by): *Radioactive Pharmaceuticals, Symposium 1965*, review by C. C. Evans, 341
- Aneuploid epithelial cells: Growth Regulatory Effects of Cellular Interaction (H. Eagle and E. M. Levine), 1102-6
- Angelakos, E. T., and King, M. P.: Demonstration of Nerve Terminals containing Adrenaline by a New Histochemical Technique, 391
- Angelov, E. Z., et al.: Early Effects of Hydrocortisone on Rapidly Labelled Rat Liver Ribonucleic Acids, 807-9
- Angielski, Stefan, and Szutowicz, A.: Tissue Content of Citrate and Citrate-cleavage Enzyme Activity during Starvation and Refeeding, 1252
- Angiotensin II in Blood: Measurement of (R. E. Morris, jun., and P. R. Robinson), 936
- Angle of the Polarization Plane of Radiosources with Time: Variation of the Positional (G. B. Sholomitsky), 580
- Angular Size and Flux Density of the Small Source in the Crab Nebula at 81.5 Mc/s (S. J. Bell and A. Hewish), 1214-6
- Animal Anaesthesia (M. Westhues and R. Fritsch), Vol. 2, review by B. M. Q. Weaver, 235
- Animal Populations with Unidentifiable Individuals: Estimation of Survey Efficiency for (S. Seierstad et al.), 524
- Animal Sonar, news, 960
- Anion in Erythrocytes: Evidence for Facilitated Diffusion of (F. R. Hunter), 816
- Anisotropic Distribution of Quasars with Large Red-shift (M. V. Penston and G. M. Rowan-Robinson), 375-7
- Anisotropy of Graphite: Optical (S. Ergun), 135
- Anstall, H. B., et al.: Inheritance and Sub-unit Composition of Haemoglobin in the Horse, Donkey and their Hybrids, 88-90
- Antarctic Lakes: Trace Element Content of (C. R. Boswell et al.), 167
- Anthracene in a Magnetic Field: Increase in d.c. Dark Conductivity of (K. Morgan and R. Pethig), 900
- Anthropology: The Savage Mind (Prof. C. Lévi-Strauss), review by A. J. Butt, 14
- Anti-Alloxan Diabetes Factor: Glucosamine Acetoacetate Condensate: a New (J. L. Padron et al.), 1254
- Antibiotic: Salmonellin—a New Colicin-like (N. Atkinson), 184
- Antibiotics: Killing of Staphylococci by Penicillins (H. J. Rogers), 31-3
- Antibiotics containing Phosphorus: The Prasimomycins (F. L. Weisenborn et al.), 1092-4
- Antibiotics *in vivo*: Sensitivity of *Trypanosoma equiperdum* to the Action of Tumour-inhibitory (J. J. Jaffe), 704
- Antibiotics on the Transplantability of Mouse Mammary Tumours: Effect of Histones, Other Basic Proteins and Some (V. C. Shah and P. Reilly), 403
- Antibodies of the ABO System and the Metabolism of Human Spermatozoa (D. R. Ackerman), 253-6
- Correlation between Net Charge of Antigens and Electrophoretic Mobility of Immunoglobulin M (J. B. Robbins et al.), 1013
- Antibodies from Mosquito Blood Meals: Identification of Host and Host (B. L. Herndon and D. A. Ringle), 624
- Antibodies to the Native Enzyme: Restoration of Enzyme Activity of Heat denatured Acetylcholinesterase by (D. Michaeli et al.), 77
- Antibodies which react with Heterogeneous Bacterial Antigen: "Normal" (F. W. Chorpennig and M. C. Dodd), 305
- Antibodies after Skin Transplantation: Synergistic Action of Antibodies: Detection of Circulating Antileucocyte (M. Gabriel et al.), 499
- Antibody: Effect of the Number of Antigens on the Quantity of Cells producing Several Kinds of (J. S. Schwartzman), 925
- Antibody Formation: Effect of Anti-rat Lymphocyte Antibody on Humoral (K. James and N. F. Anderson), 1195-7

- Antibody-forming Cells by RNA: Conversion of Non-immune Cells into (E. P. Cohen), 462-5
- Antibody Production by Phytohaemagglutinin: Suppression of (M. W. Elves), 495

## THE TECHNOLOGY GAP

A GREAT deal of well-intentioned nonsense is to be heard about the phenomenon called the technology gap, and there is a danger that it is infectious. The assertion is that Europe lags behind the United States in technological prowess, that the gap is steadily increasing, and that some means should be found for making it melt away. The Italian Government first raised the banners of deprivation early in the autumn of 1966. Mr. Harold Wilson, the British Prime Minister, echoed with a vision of how Britain could contribute more than most nations to the creation of a technological community in Western Europe. Towards the end of the year, both the President of the United States and the secretariat of the OECD embarked on special studies, and just before Christmas the issue came up in the Council of the North Atlantic Treaty Organization. Evidently the months ahead will be fully occupied with committee meetings of all kinds. Unhappily there is nothing like the same assurance that there will be agreement on whether there is a phenomenon which can be described as a technology gap, whether if it exists it is to be deplored or counted a blessing, and how, if at all, it might be removed or at least diminished.

The first need is to know what problem should be tackled. Although there is no reason to think that Europe is intrinsically incapable of some of the technological feats now being carried out in the United States, the plain fact is that advanced technology is much less obvious in Europe. But there is a similar disparity between Europe and North America in the general level of industrial production, in personal incomes (which determine the sizes of markets for goods of all kinds), and even in the amounts of food consumed. And if Europe sometimes looks a little woe-begone in comparison with the United States, it nevertheless seems unattainably sophisticated in comparison with the developing nations and those which are hardly developing at all.

In all these comparisons, the problem is to decide which comes first—the prosperity or the technology. By now there is plenty of evidence that technological developments alone do not bring prosperity. The collaboration of European nations in the development of the European space launcher under the umbrella of ELDO is unlikely to add much to the industrial competitiveness of the member countries. Certainly there would have been a better return from the investment of £100 million or so in more pedestrian development work—computers or even diesel engines, for example. Equally, the decision to commit £500 million to the Anglo-French development of a supersonic aircraft is unlikely to yield that amount of

benefit to the economies of the countries concerned. And even in the United States, it may well turn out that the Apollo programme to put a man on the Moon will prove to be more a drag on the economy than an incentive. What is called spin-off is grossly overvalued. The moral in all these cautionary tales is that lasting technological success depends on the existence of a healthy demand for its products. From this point of view, it is encouraging that the British Government seems to conceive of its European technological community in the context of the Common Market.

What, then, is likely to be done in Europe? Much more should be known about the British contribution after the Prime Minister and the Foreign Secretary have trudged around the capitals of the members of the European Economic Community in the next few weeks. No doubt they will make as much as they can of the contribution that British technology could make to the pace of development in Europe as a whole, and that will be entirely proper. But even if their enquiries result in a cheerful forecast about British and Scandinavian membership of the European Community, there will be a great deal of solid drudgery ahead. Working out common procedures for industrial specifications, testing procedures and patent applications will be a necessary preliminary—and progress on these matters within the Common Market has not been nearly as rapid as was at first expected. It would not be surprising if the amendment of national company legislation turned out to be high on the list of humdrum needs, together with arrangements for helping skilled people to move more easily from one place to another. At this stage, there is much less scope for the more ambitious schemes which are sometimes talked about—although there is a great deal which could be done immediately to put public laboratories more freely at the disposal of Europe as a whole. But none of these devices, and the more ambitious schemes which might follow, will work if the economic climate is not right. Mercifully, nobody seems to think that Europe can be turned into an engineers' Aladdin's Cave by investing money and effort in spectacular technology.

## ONE BASKET FOR EGGS

WITH the possible exception of a few men in Seattle, nobody will cry chicken because President Johnson and the United States Government have not followed the choice of the Boeing Aircraft Company as super-

sonic constructor to the administration with a decision that funds should be committed to the construction of a supersonic civil aircraft. For one thing, of course, this is a bad year for raising money, so that a decent show of diffidence in asking Congress for large sums of money is prudent as well as seemly. And in any case—a more practical consideration—there is \$200 million left in the kitty from last year, which should keep the design teams at Boeing employed for a month or two yet. Certainly there are enough problems to keep them busy, for all the consequences of the substantial modification of the design halfway through 1966 have not yet been fully worked out. As much as a year may be needed before all the details are tidied up. The President may have picked his gladiator, but there is no need to give him marching orders for a month or two.

A breathing space, however short, may help partially to resolve some of the problems which still haunt the supersonic projects now going forward in Europe and the United States. The strictly technical problems are probably the least worrying, which is not to imply that they are anything but formidable. The Boeing version of the supersonic transport is particularly ambitious. At take-off, lift enough for 300 tons or so of titanium and aviation fuel, with human appendages, will have to be transmitted through two wing hinges which must nevertheless perform so accurately that they do not become lop-sided in movement and turn the aircraft upside down. But, if the engineering will be difficult, it will also be fun. On strictly technical grounds, it is better that the Boeing design should have been chosen in preference to the more conventional solution proposed by Lockheed.

But getting off the ground will be easier than winning the right to do so regularly. Supersonic flight could easily turn out to be an intolerable public nuisance, with the result that operations of certain kinds are entirely forbidden. Even if supersonic flights over land areas are allowed, however, they are bound to be hedged around with restrictions more severe than those which at present keep the operators of subsonic jet aircraft lying awake at nights. Sometimes it may be necessary to build new airfields for supersonic aircraft, which will also help to tip the economic balance against them. But all this implies that all the supersonic projects, European and American, are gambles of a kind.

The simple commercial uncertainties of supersonic transport aircraft are even more daunting, and not merely because it is hard to see that the development programmes will pay for themselves. In Europe, indeed, the British and French Governments have apparently now abandoned hope that sales of Concorde aircraft will recover more than a nominal part of the £500 million to be spent on development. In the United States, no doubt, one of the issues to be hammered out in the next few months is that of how the administration and the Boeing company should share the risks and the putative profits of the programme that lies ahead. The most obvious difficulty on this score is that of knowing what the fare-paying demand for seats in supersonic aircraft will be. The Boeing

company may be right in its cheerful estimate that the demand for air transport will turn out to have doubled in the last half of the present decade, and there is every reason to expect that the rapid growth of air transport in the last two decades will continue for at least as long again, but that does not necessarily mean that people will pay the extra costs of travelling supersonically. Ironically, the Boeing company itself has chosen to invest an unprecedented amount of private capital in the construction of a line of jet aircraft capable of flying faster than any now in service and with twice as many passengers. As yet, it is too soon to know which of these will emerge as the more successful.

## NATURE BY AIR

BEGINNING with this issue of *Nature*, most subscribers to this journal in North America will be supplied each week with a copy which has been flown across the Atlantic by air freight and then distributed from New York by surface mail. The result will be that the journal should reach subscribers in the United States and Canada very soon after publication in London. Many subscribers in the United States will find that the journal reaches them on the date printed on the front cover—a circumstance which owes something to the near identity of the transatlantic time difference and the time taken for a jet aircraft to make the journey.

It is appropriate that there should be some kind of symmetry between the two sides of the Atlantic, for the numbers of copies distributed in the United States and the United Kingdom are approximately the same. (With Canada counted in, the centre of gravity lies somewhat to the West of mid-Atlantic.) But there are more cogent reasons why the delay in shipping the journal across the Atlantic by sea should have become intolerable. The increasing pace of change in science, and the urgency of a good many scientific communications, would be in themselves sufficient reason why copies of a weekly journal should not at the beginning of their useful life be incarcerated for two weeks or more in the hold of a ship. But periodicals of all kinds are more than mere providers of information. They serve also to give those who read them something which can properly be called a sense of community. (Readers know that at the least they have what they read in common.) But those who see their periodicals late tend to feel excluded from an experience which others have enjoyed. This, certainly, is why out of date newspapers are so hard to read. *Nature* seeks to provide the whole profession of science with a continuing and informed discussion of events as well as with a record of discovery, and therefore has a particular responsibility to be easily and quickly accessible. Sending it by air across the Atlantic is one of several steps which have been taken in the last century, and which will be taken in the next, to make it of greater service to those who read it.

## NEWS AND VIEWS

### What Future for Trieste?

THERE is continuing uncertainty about the means that will be found for financing the International Centre for Theoretical Physics at Trieste, at present sponsored jointly by the International Atomic Energy Agency at Vienna and the Italian Government. Although the centre has been widely acclaimed as a success, it appears that it may be hard for the IAEA to shoulder the chief cost of running the institution when the Italian Government withdraws its present support, originally intended to put the centre on its feet and not to support it indefinitely.

In the most recent annual report on the work of the International Agency's laboratories, the total budget of the centre at Trieste is given as \$414,447. Of this total, the contribution of the Italian Government amounted to \$278,000, while the International Agency contributed \$55,000. In addition to its contribution towards the running costs of the centre, the Italian Government has also provided the buildings in which the centre is housed. Because more than half the budget of the centre goes on salaries, there is obviously very little room for substantial economies without a drastic reduction of the scale of operations.

It is, however, unthinkable that the centre should founder for lack of support. The staff numbers close on a hundred, with Professor Abdus Salam as director. The centre has also pioneered a system of associate-ships under the terms of which physicists from countries described as "scientifically isolated" spend up to four months in the year at the centre. The work of the centre is organized into two divisions concerned with high-energy physics and plasma physics respectively, and an important part of the work of each of them is the organization of seminars lasting several weeks.

The central impediment to the continued financing of the centre by the International Agency is that there is no readily recognizable heading in its budget to accommodate what happens at Trieste. When the centre was formed two years ago, largely as a result of the enthusiasm of Professor Abdus Salam, it seemed that it would make an outstanding contribution to the training of physicists from developing countries, so that the agency was able to justify its modest support of activities at Trieste under the heading of aid. Experience has shown, however, that although the centre does include many people from developing countries on its staff and among its research fellows, its most valuable role is as an international meeting centre for physicists of all nationalities. In the circumstances, it is not surprising that Unesco has been suggested as the most natural source of continuing support. It is not yet clear whether that organization will choose to carry on the torch.

### Unfamiliar Modesty

MERELY a modest increase in expenditure on research and development in the United States is predicted by the Batelle Memorial Institute in its annual forecast

for the calendar year 1967. Total expenditure is expected to reach \$23.8 billion, an increase of only 2.2 per cent over 1966. This is the smallest percentage increase in the thirteen years for which records are available, and the dollar increase of \$500 million is the smallest since 1955.

The Batelle Institute is not, however, quite as clairvoyant as it may seem. It has been known for some time that Federal spending, the dominating factor in research and development—providing nearly 70 per cent of the funds—was not going to maintain its dizzy upward climb in 1967. The slowdown in Federal spending means that for the first time in ten years, industry, universities and non-profit institutions make up the major part of the annual increase—some 80 per cent. Industry, Batelle predicts, will spend \$6.8 billion, universities \$480 million, and other non-profit institutions \$326 million.

The figures show a shift in emphasis of the Federal research budget. The only component likely to get more money is basic research, with estimates of \$1.7 billion in 1965, \$1.9 billion in 1966 and \$2.1 billion in 1967; reductions are forecast for investment in plant and expenditure on applied research and development. The big spenders have been pinched hardest—the Department of Defense (DOD), the National Aeronautics and Space Administration (NASA) and the Atomic Energy Commission (AEC). Beneficiaries have included the Department of Health, Education and Welfare, the National Science Foundation, and the Departments of Agriculture, Interior and Commerce, but their increases hardly reflect the kind of commitment to the problems of health, air and water pollution, urban transport and re-development which is necessary if the aims of the "Great Society" are to be realized. What is particularly unfortunate is that if it were not for budgetary pressures, the lull in spending by DOD and NASA might have made possible a real re-distribution of funds.

By the time the budget pressure is relaxed, and the war in Vietnam settled one way or the other, DOD and NASA may well be clamouring for money once again. NASA has most of the money it needs for the "Apollo" programme, and seems uncertain what it wants to do after that, but nobody doubts that whatever it does decide to do will be very expensive. The Department of Defense is facing the problem of whether to establish an anti-missile defence system, with a budget of frightening size; estimates run between \$30 billion and \$50 billion. Another appropriation being deferred month by month is that for development of the Boeing supersonic transport. To put this into service is likely to cost \$4 to \$5 billion, with a Federal contribution of at least 75 per cent. It does begin to look as if the budget is simply not going to stretch far enough. The loser, especially after the mid-term election results, seems likely to be the Great Society.

### New Year Re-shuffle

SIR WILLIAM PENNEY is to leave the U.K. Atomic Energy Authority in September to become the next Rector of the Imperial College of Science and Technology—a post left vacant by the death of Sir Patrick Linstead three months ago. Sir William thus returns to academic life and his old college after an interval of 23 years in nuclear research and development,

most of it in weapons research, first as British representative at Los Alamos and then as Director of Research at Aldermaston. His three years as chairman of the Atomic Energy Authority leave it well organized and successful. It is now likely to enter a period of contraction and change which will impose an even greater burden on the new chairman.

It is also known that Sir Harry Melville is retiring in September from his post as Chairman of the Science Research Council. He has been chairman of the council since it was established in April 1965, was previously Secretary of the Department of Scientific and Industrial Research, and has been professor of chemistry at both Aberdeen and Birmingham. He too will probably wish to return to academic life. The name of Professor B. H. Flowers has been frequently mentioned in speculation about his successor at the Science Research Council.

## Nuclear Information

THE International Atomic Energy Agency is about to launch an ambitious scheme for collecting and processing technical information on atomic energy. At the end of December a working party drawn from sixteen of the member countries of the agency accepted in principle what is described as the concept of "an international nuclear information system", and which has already been blessed with the acronym INIS. The International Agency has for some time been concerned to sponsor developments in the handling of information in nuclear physics, and has been carrying out some work within its own organization. No doubt the new organization will work closely with others such as the Neutron Cross Section Centre in Paris which is operated by the European Nuclear Energy Agency.

## Aid Distribution

THE O.E.C.D. in Paris has now published statistics showing the way in which financial aid from advanced nations is distributed to developing countries. According to figures based on the membership of the Development Aid Committee of the O.E.C.D. (which includes Australia and Switzerland as well as the ordinary members of the organization), the total financial contribution to the less developed countries between 1960 and 1964 amounted to \$42.3 billion. Of this total, governments contributed \$25.9 billion, or close on two-thirds. The contribution of multilateral agencies such as the various institutions of the United Nations amounted to \$2.3 billion, and the rest of the aid represented the investment of private companies in the economies of developing nations.

It appears that the members of O.E.C.D. have put Asia at the top of their list of recipient countries, for the flow of public money to Asian countries worked out at an average of \$2,315 million a year in the first five years of this decade. Africa comes next on the list with an average of \$1,523 million a year from government sources. In terms of the populations of the two regions, of course, Africa is the more generously treated in that its population of 280 million people is merely a third of that of the recipient nations in Asia. Aid to Latin America and to undeveloped countries in Europe took \$674 and \$438 million a year respectively in the first five years of this decade. Except

in Asia, aid giving appears to be more or less the same from one year to the next, although the present contribution to the economy of undeveloped countries on the American continents is much greater than it was in the fifties.

## Publishing in Physics

THE Institute of Physics and the Physical Society, which has a long-standing interest in publishing of all kinds, is now planning to publish on its own account records of its own conferences and symposia. Three volumes, relating to conferences held in September, 1966, have been or are about to be published at prices ranging from £4 4s. to £5. Evidently the institute is hoping that it will be able to publish symposium proceedings more quickly and more cheaply than commercial publishers. Another of the benefits of the arrangement will be that librarians and others will be able to trace the publishers of particular conferences more easily than at present. Other learned societies will no doubt follow the experiment with interest.

## Less Smoking in Britain

A SIGNIFICANT decline in the consumption of tobacco in the United Kingdom is recorded in the fourth edition of the survey on the subject carried out each year by the Tobacco Research Council. Between 1964 and 1965, the total consumption of tobacco fell by four per cent to 255.1 million pounds. Since 1961, when smoking was at its peak, there has been a decline of eight per cent, coupled with a substantial change in smoking habits in favour of cigars and against pipes and cigarettes.

The decline is more marked when expressed in terms of the consumption by individuals, and among adult male cigarette smokers consumption declined from an average of 4,010 cigarettes per head in 1961 to 3,580 per head in 1965. The rising trend of cigarette smoking among women since the mid-fifties has now apparently been halted, and has settled down at 1,860 cigarettes per head or roughly half as much as for men. The incidence of cigarette smoking among children between 10 and 15 years seems not to have changed significantly in the first half of the present decade, but the numbers of men smoking tobacco in all its forms have declined significantly between 1958 and 1965, particularly among the age groups above the mid-thirties. Thus the proportion of men between 35 and 49 not smoking tobacco at all increased by nearly a third between 1958 and 1965, and amounted to 30 per cent at the end of the period. Although the proportions of women smokers are consistently lower than those of men in the same age groups, there has been no corresponding decline in the incidence of smoking in the years covered by the survey.

## Britain Five Years Ago

THE spate of primary publications of the 1961 census of the British Isles may soon be coming to an end, to judge from the appearance at the end of 1966 of the Summary Tables for Great Britain, together with the Household Composition Tables for England and Wales (H.M.S.O., £1 19s. and £3 7s. respectively). The

tables are comprehensive, careful and rather out of date.

The Summary Tables include details of population, age and marital condition, birthplace and nationality, fertility, migration, occupation, household composition, and age of leaving school. The population of Great Britain in 1961 was 51.35 m, made up of 24.7 m males and 26.6 m females, which represents a doubling of the population since 1870. Some of the tables are based on a complete return, while others are based on a 10 per cent sample. For these, sampling errors are defined. Even a 100 per cent return is no guarantee of accuracy, however, as the tables show. In 1961 for the first time a post-enumeration survey was carried out to check the information collected at the census; this shows that in some cases the information given in the census returns was inaccurate. The reasons for the inaccuracies are not given, but presumably they are caused either by ambiguities in the census form, or by simple reluctance of the people filling in the form to admit the truth. The number of women in employment, for instance, was understated, as was the number of households without a water closet. 1.08 m households without a water closet seems a remarkably high figure, but is likely to be an underestimate; the post-enumeration survey showed that the figure might be nearer 1.5 m. Facts like these show the great interest of the census returns; they would be easier to read, though, if they had better indexes.

## Transports of Despair

THE British Ministry of Transport must be feeling baffled by the sharp rise in road casualties over the Christmas holiday. Just two days before the holiday began, the Ministry issued figures for September 1966 which show that for the fourth successive month fewer people were killed and injured on the roads. In September there were 31,911 casualties, a figure which hardly gives cause for dancing in the streets, but which is nevertheless a reduction of 7 per cent compared with September 1965 despite a 7 per cent increase in traffic density since then. By contrast, the three days of the Christmas holiday showed an increase in casualties from 2,853 to 3,335 (17.5 per cent), and of deaths from 55 to 80.

Both sets of figures are worth closer examination. Over the Christmas period the number of injuries was actually produced by fewer accidents than last year—indeed, the Ministry of Transport figures show 5 per cent fewer accidents for Christmas 1966. A number of inferences can be drawn from this, but the most obvious way in which the number of people involved in each accident is increased is by increasing the number in each car. In response to the appeal not to drink and drive, people may well have left their cars at home and taken lifts with friends, a course of action long recommended by the ministry and the motoring organizations. If this interpretation is correct, minor injuries should show a much steeper rise than major injuries, since the back seats of cars are much safer than the front. In fact, this is exactly what did happen; slight injuries increased by 22 per cent, serious injuries by only 2.5 per cent. Of course, it is risky to interpret the figures without more detailed information; interpretation is really the job of the ministry.

The ministry attributes the improvement in the

September figures to the decline of two wheeled vehicles. The mileage covered by bicycles has declined for some years, and since 1960 the mileage covered by mopeds, scooters and motor bicycles has also declined. For every mile travelled, users of two wheeled vehicles suffered ten times as many fatal and serious injuries as drivers of cars, so the switch to safer vehicles has brought about a reduction in casualties, although the casualty rates for individual classes of vehicle have in many cases increased. To be sure, this conclusion will confound no one but the scooter manufacturers, but people are entitled to ask the ministry one plaintive question. Why, if two wheeled vehicles are so dangerous, does the ministry encourage their sale by letting young people ride them for a year before they are considered old enough to drive a car?

## Supersonic Contract

THE complex problem of deciding which of the two claimants to the U.S. Supersonic Transport contract has produced the better design has been settled to the satisfaction of the Federal Aviation agency, President Johnson and the Boeing Aircraft Corporation. The agency has selected the Boeing swing-wing design in preference to the Lockheed double-delta, and engines by the General Electric Company rather than Pratt and Whitney. The decision came as no great surprise, for the airlines consulted by the agency were reported to prefer the Boeing design.

The supersonic transport battle now resolves into one between the Boeing design, with a speed of 1,800 m.p.h. and room for up to 350 passengers, and the Anglo-French Concord, which will carry 136 passengers at 1,450 m.p.h. In the background, competing for prestige if not economic gain, is the Russian Tu144, which has a specification remarkably similar to that of Concord, carrying 126 passengers at 1,500 m.p.h. The Boeing design, which will cost \$35 m against the Concord price of \$16, is clearly the most ambitious of the three, but is three years behind the other two; both the Russian and the Anglo-French designs are to make their first flights in 1968, while the Boeing design is still at the mock-up stage, and earlier this year underwent radical design alterations.

The striking feature of the Boeing design is the use of wings which swing from a position at right angles to the fuselage at take-off through an intermediate position while climbing at subsonic speed and finally link up with the tail to form a delta-wing for high altitude cruising. Boeing claims that this design concept is well tested and proved, although some airlines are reported to have expressed alarm about it. It undoubtedly improves efficiency, particularly in take-off and landing, but the engineering which it makes necessary adds weight and offsets some of this advantage. In fact the take-off and landing speeds and distances required by the two rival American designs are remarkably similar; where the Boeing design would presumably gain would be in using the engines at lower power when circling and landing, a reduction both in cost and in annoyance by noise.

The problem of noise may well turn out to be more significant than is usually realized. It is already being seriously suggested that certification of aircraft should include permitted noise levels, and while this is unlikely to happen next week, it could be a reality in five

years' time. By that time Concord will be operating, and is unlikely to be trapped by noise legislation. If the noise level established means that the Boeing aircraft has to fly more slowly than its design speed, economy of operation will suffer severely, and indeed may make the SST quite uneconomic over land. A study commissioned by the FAA and carried out by the North American Aviation Co., however, indicates that the penalty of flying SSTs at subsonic speeds over land would be "not intolerable". People's interpretation of this depends on whether they build aeroplanes or operate them.

Aircraft builders are, of course, notoriously optimistic. This optimism is not always shared by the airlines, or by the political paymasters of the aircraft industry. The sacking of General Puget, until last week head of Sud Aviation, the nationally owned French airframe company which is collaborating with the British Aircraft Corporation in the Concord project, will diminish by one the number of enthusiasts in service. General Puget's successor, M. Maurice Papon, is known as a gifted administrator.

## Swinging Wings

BRITISH aerodynamic engineers are at once envious and optimistic about the outcome of the development work to be carried out by the Boeing Aircraft Company before its supersonic aircraft can take the air. The problem of matching the two wings together in such a way as not to upset the lateral stability of the aircraft has been dealt with on the F111 fighter aircraft by linking the two halves of the wing together mechanically with a common jack. Because the Boeing design has separate hinges for each half wing, and because these lie athwart the passenger cabin, it will be necessary to link the two halves together with an electro-mechanical servo-system. Apparently even as much as a degree or so of mis-alignment between the two wings would not be beyond the capacity of the roll control system, partly because the outer surfaces of wings contribute only a small proportion of the total lift.

The problem of designing hinges which can move reliably and yet transmit lifting forces comparable with the weight of the aircraft appears also not to be a cause for worry. Prototypes of hinges with dry bearings and lubricated bearings have been carried out. There appear to be no problems in using materials such as PTFE as dry lubricants or in using ordinary petroleum lubricants. Problems arising from the high temperatures at which some supersonic designs will operate may be more serious, particularly because they make it necessary to introduce new materials for incidental purposes such as the operation of hydraulics and lubrication systems.

Aerodynamic engineers therefore remain preoccupied with problems closer to the mainstream of classical aerodynamics. Thus it is necessary to design supersonic aircraft such as the Boeing SST so that they can if necessary land with the wings fully swept back if, for some reason, the wing moving mechanism should fail. In this kind of mishap, supersonic aircraft would necessarily have to seek out airfields with long runways and use up spare fuel before attempting to land at what would inevitably be a hair-raising landing speed. Another problem which excites lively interest

is that of striking a continuing balance between the centre of aerodynamic lift and the centre of gravity of a supersonic aircraft with swept wings. On the face of things, it would appear that moving back the wings would leave the front of an aircraft unsupported. British aerodynamicists claim that a decade ago Dr. Barnes Wallis showed that a clever distribution of the weight of an aircraft could go a long way to reduce the severity of this problem.

## Venus Observed

THE first observations of water vapour in the atmosphere of Venus from ground based observatories are described in two notes published in the current issue of the *Astrophysical Journal*. Hitherto, the identification of water in the atmosphere of Venus has been based on observations from balloon flights over the United States in the early sixties. Both the groups now reporting have worked with water vapour absorption lines in the near infra-red (8189 Å and 8193 Å) and have been able to recognize Doppler shifts due to the motion of Venus at different parts of its orbit about the Sun. The detection of water vapour in planetary atmospheres is necessarily complicated by the presence of water in the atmosphere of the Earth, but Doppler shifts make it possible to separate absorption due to the two sources.

M. J. S. Belton and D. M. Hunten worked with spectra of Venus formed by the 40 ft. spectrograph of the solar telescope at the Kitt Peak National Observatory (*Astrophysical Journal*, 146, 307; 1966). The second note in the same issue of the journal (*ibid.*, 146, 328; 1966) is by Hyron Spinrad and Stephen J. Shawl of the University of California at Berkeley, who have examined coude spectrograms of Venus taken at the Lick Observatory. The Doppler shift of the spectra due to the movement of Venus in its orbit amounted to between 0.2 and 0.3 Å, and the successful identification of water vapour from the Earth has thus been made possible only by the extremely high dispersion of the spectrographic instruments used. Both groups of astronomers have been able to estimate the amount of water in the atmosphere of Venus above the clouds. The first group has set an extreme upper limit of 125 microns to the amount of precipitable water, and the second has estimated the amount of water at 60 microns, emphasizing that this estimate is necessarily somewhat crude.

## Luna 13

LUNA 13, the Russian spacecraft which made a soft landing on the Moon on December 24, 1966, has now completed its mission. Pictures taken by Luna 13 from the landing site in the Ocean of Storms, 250 miles from the site where Luna 9 landed, show that there are no formations larger than 3.5 km in diameter within 62 km of the landing site, and no big formations rising above the ground. The spacecraft, inclined at 16° to the local vertical, completed a panoramic sweep and was able to distinguish objects 1.5 to 2 mm in size at a distance of 2 m. The spacecraft contained electronic programme devices, chemical batteries, and a temperature regulating system, and had four petal and four rod antennae, a television camera, and two devices for measuring soil depth and density.

The results seem to have confirmed those obtained by Luna 9. The level of radioactivity on the Moon's surface is low, and measurement of the cosmic ray reflectance of the surface shows that the Moon reflects 25 per cent of the particles which fall on to it from space. Photography showed once again that there is no layer of dust on the Moon's surface, which is covered with small stones a few centimetres in diameter. The Russian results suggest that these stones had fallen quite slowly onto the lunar surface and were certainly not meteorites, which would have given cratering.

In addition, Luna 13 carried out measurements of the physical properties of the surface. Rods were driven into the ground by an explosive device to a depth of 20-30 cm, and the density was measured by a beam of gamma radiation distributed along the surface. These measurements show that the surface of the Moon has mechanical properties similar to the properties of terrestrial soil of medium density. The density of the surface is much less than that of the Earth, and much less than the average density of the Moon.

## Economic Geochemistry

GEOCHEMISTRY is still struggling for a place in the hierarchy of recognized sciences. After the Second World War the subject promised to be an important tool for economic geologists, but this promise has not been fulfilled and the techniques of geochemistry have so far been principally used for such tasks as tracing the movement of underground water and prospecting for uranium. The investigation using geochemical methods of the Pequop Mountains area in Elko County, Nevada, by the U.S. Geological Survey is therefore welcome (*U.S. Geol. Survey Bull.*, 1198-E, 1966). The area had no previous history of metal production but possessed a host rock type (dolomite) and a structure favourable to the formation of ores. Conventional sampling and analysis of stream sediments failed to reveal anomalously high concentrations of metals, but analysis of river cobbles and pebbles showed contents of more than 1 per cent of lead and zinc, with lesser amounts of mercury, antimony and arsenic. The metals were concentrated in iron rich fracture fillings or gossan pods (with or without barite), both of which were associated with silicified limestone. Only detailed mapping will reveal whether these metals are present in commercially exploitable amounts.

## Crater in the Lake

A SWEDISH geologist has suggested that a submerged circular depression in Lake Hummeln, 150 miles south-west of Stockholm, was caused by the impact of a meteorite some 600 million years ago (Svensson, N. B., *Sver. Geol. Unders. Afh.*, 60, part 3, 1966). The crater, which is excavated in Pre-Cambrian granite, was probably exhumed by ice during the Ice Age. Evidence for a meteoritic origin is the presence of an unconsolidated breccia composed of pieces of the granitic basement and the shape of the crater, which is flat bottomed with a pronounced rim. It is thought that shortly after the formation of the crater the area was covered with Pre-Cambrian sandstone, thus preserving a feature which, if it had been exposed to the elements, would have rapidly become unrecognizable. A vol-

canic origin for the crater is improbable as no contemporary volcanic activity is known in the area, while a tectonic origin is ruled out on the grounds that the last demonstrable tectonism in the area was some 500 million years earlier than the formation of the crater. If the depression in the floor of Lake Hummeln is indeed an impact crater, then it is one of the earliest examples in the geological record.

## Sound of the Walrus

THE sounds made underwater by Olaf, a ten year old Atlantic walrus (*Odobenus rosmarus*), have been recorded at the New York Aquarium. The sounds can be heard on a gramophone record which is included in the latest edition of *Zoologica*, published by the New York Zoological Society.

The underwater sounds are distinct from the bellow, grunt and mellow whistle made by the walrus in the air. Underwater, the walrus produces rasps, clicks and bell-like sounds, with mouth closed and head submerged. The rasps and clicks are of short duration, 0.1-0.2 sec and 0.015-0.020 sec respectively. The clicks are produced in rapid sequences and resemble quiet machine gun fire. The rasp is the type of noise which is produced by blowing through closed lips. Olaf, with a damaged eye, had no difficulty in swimming, even with eyes closed. The rasps and clicks which he emitted in the process could have been for echo-location; but, as the report points out, the walrus was in familiar surroundings and may have been relying on memory for his orientation.

The bell like sound lasts longer (1-1.5 sec) than the rasps or clicks and is hollow and metallic, like the sound of distant cymbals. It is associated with the development of the pharyngeal pouches, which can inflate to balloon like proportions on each side of the head of this animal and which help in floating. The walrus floats when it is sexually active, and it was on such occasions that the bell like sound was heard. Confirmation that the pharyngeal pouches act as resonators for this sound was also obtained at the death of a walrus with a pouch inflated, after a hunt by Eskimos; when the pouch was stripped of skin and fat and struck with the flat of a knife blade, a bell like sound almost identical with that recorded was heard.

## Dorcas Gazelles

L. I. Ghobrial and J. L. Cloudsley-Thompson write from the Department of Zoology at the University of Khartoum about their recent note on the effect of water deprivation on the Dorcas gazelle (*Nature*, 212, 306; 1966). "We are disturbed to learn that some readers thought that the death from drought of two experimental animals was caused deliberately. Humanitarian reasons apart, the loss of these valuable gazelles was a severe blow to our programme of research. We never expected that death would follow a percentage loss of body weight so small compared with what the camel and the sheep can tolerate. As soon as our animals became weak and a big increase in blood urea was noted, they were given water and salt. Despite this, they died after about 12 h. We are sorry if our purely factual statement has misled your readers."

## University News:

## Liverpool

DR. M. R. SAMPFORD, at present senior principal scientific officer in the Agricultural Research Council Unit of Statistics in the University of Edinburgh, has been appointed to the newly established chair of mathematical statistics.

## London

PROFESSOR G. L. HOWE, professor of oral surgery in the University of Newcastle upon Tyne, has been appointed to the chair of oral surgery at the Royal Dental Hospital of London School of Dental Surgery from April 1, and Dr. M. Ginsburg, reader in pharmacology at Chelsea College of Science and Technology, has been appointed to the chair of pharmacology, tenable at that college.

## Southampton

DR. J. H. BIRD, reader in geography in University College, London, has been appointed to the chair of geography in succession to Professor F. J. Monkhouse; and Dr. M. Fleischmann, reader in physical chemistry in the University of Newcastle upon Tyne, has been appointed to the Electricity Council Faraday chair of electrochemistry.

## Appointments

DR. V. SUNDARAM, formerly senior scientific officer of the Cotton Technological Research Laboratory, Matunga, has been appointed director of the Cotton Technological Research Laboratory, Bombay.

## Announcements

DR. BRYAN THWAITES has been elected president of the Institute of Mathematics and its Applications for 1967, in succession to Professor M. J. Lighthill. Dr. Thwaites is principal of Westfield College in the University of London and is well known for his concern with the improvement of mathematics teaching in schools and for his founding of the Schools Mathematics Project. Professor Lighthill, Royal Society Research professor at Imperial College, London, and formerly director of the Royal Aircraft Establishment, Farnborough, played a major part in founding the institute, and has been its president since its incorporation in 1964. Dr. E. T. Goodwin, superintendent of the Mathematics Division of the National Physical Engineering Laboratory, and Dr. P. G. Wakely, manager of the Mechanical Engineering Laboratories of the English Electric Co., Ltd., at Whetstone, Leicester, have been appointed vice-presidents of the institute in succession to Professor A. Geary and Professor K. Stewartson. Professor D. C. Pack will continue to serve as honorary treasurer and Mr. F. W. Kellaway and Mr. W. G. Sherman as honorary secretaries.

At the election for the first elected council of the British Acoustical Society, which took place in November, Professor R. E. D. Bishop, Kennedy professor of mechanical engineering in University College London, was elected president. The other elected officers are: *Vice-presidents*, Professor E. J. Richards (head of Institute of Sound and Vibration Research, Southampton); Professor E. C. Cherry (Department of Electrical Engineering, Imperial College of Science and Technology, London); Mr. W. A. Allen (consulting architect).

DR. ELI BROOKNER, of the Raytheon Company, is the first recipient of the Journal of the Franklin Institute's \$1,000 award, which is to be made annually to the author of the outstanding paper appearing in the journal during the preceding year. Dr. Brookner received the award for his paper entitled "Effect of Ionosphere on Radar Waveforms", which deals with the problem of determining the effects of the ionosphere on the propagation of microwaves.

A MONTHLY abstract journal entitled "Abstracts of Mycology" is being published by BioSciences Information Service from January this year. There will be three trial issues, circulated to individual scientists with known interests in this specialized field of study. Further information can be obtained from Abstracts of Mycology, Professional Services and Education Department, BioSciences Information Service of Biological Abstracts, 2100 Arch Street, Philadelphia, Pennsylvania, 19103.

**ERRATUM.** In the legend accompanying Table 1 of an article "Induction of Thymine Dimers in Synchronized Population of Chinese Hamster Cells" by D. L. Steward and R. M. Humphrey (212, 298; 1966), the word "uridine" replaced the word "uracil" at two points, the words "cystine or cysteine" replaced the word "cytosine" at one point and the legend should read: "The two dimensional chromatographic analysis (ref. 8) does not separate uracil-thymine dimers from thymine dimers and the activity of both photo-products is referred to as thymine dimer activity in this report. The uracil-thymine dimer arises from the cytosine-thymine dimer deamination during acid hydrolysis of the DNA (ref. 17)".

**ERRATUM.** In the article "Flame Ionization and Magneto-hydrodynamics" by Jean Debiesse and Siegfried Klein in *Nature*, 212, 1405 (1966), figure 4 was printed upside down.

**ERRATUM.** In the first sentence of the third paragraph in the obituary of Dr. Arthur Patterson in *Nature*, 212, 1414 (1966), "increases" should read "decreases".

## CORRESPONDENCE

## What Kinds of Cities?

SIR,—Your article thus headed seems to me an odd compound of scientific scepticism and unscientific assumption. It rebukes the Greater London Council for neglect of research into what city people like, what they will put up with, and what they might like if they knew about it. Then in the belief, or hope, or hunch (which is it?) that closer packing in flats of 6 to 49 stories would be socially and culturally better, it accuses the G.L.C. of neglecting to consider that form of housing.

But this matter of high versus low housing happens to be one on which there has been the most exhaustive research; innumerable surveys and opinion polls have shown that 85 to 95 per cent of British people dislike flats and want houses with private gardens. The G.L.C. itself admits that London should have built 75 per cent of houses instead of 75 per cent of flats. Even you, without research, sense that London is too big; and I, as a proponent of a policy of decongestion and dispersal and an experimenter in its practicability, snarled at the L.C.C. for 40 years for not pursuing that obviously sensible policy. Even now that the G.L.C. is trying to do so I have to urge it to be speedier and more logical about the job, in co-operation with the Government and other regions. I know it wants to, and I realize the enormous political and technical difficulties.

London is the first great city in the world to set about reducing its population, over-centralization and density. As one of its persistent critics, I resent on its behalf the suggestion that through lack of research it is ignorant of the major social considerations.

Yours faithfully,

FREDERIC J. OSBORN

# Lunar Air Tide

by

B. HAURWITZ\*

S. CHAPMAN†

National Center for Atmospheric Research,  
Boulder, Colorado

Lunar tides in the oceans are familiar and easy to observe. Lunar tides in the atmosphere also exist, although their recognition is more difficult

THE atmosphere, like the oceans and the solid Earth, is subject to the tidal forces of the Sun and Moon. We can observe and measure the tides of the oceans and of the solid Earth at their upper boundary, where we live. The atmospheric tides have to be determined mainly at the bottom of the atmosphere. One way in which this is done is by recording the changes of barometric pressure  $p$ , which indicates the total overlying mass per  $\text{cm}^2$  column. The analogous method of measuring the ocean tides would be by a pressure gauge on the ocean bed. In this case, in mid-ocean, the fractional tidal variation of pressure would be of order  $10^{-4}$ . This is because the tidal amplitude there is of order 0.5 metre (although at many places on coasts it is much greater), whereas the mean oceanic depth is of order 4,000 m. In the atmosphere near the equator, where the lunar air tide is greatest, its pressure amplitude is about 1/12 mbar, which is likewise about  $10^{-4}$  of the pressure at sea level (approximately 1,000 mbar). The lunar air tide, like the sea tides, also involves tidal currents and can therefore be studied by determining the lunar daily variations of the wind components.

The Moon's tidal force on the Earth is 2.4 times that of the Sun, and in the oceans the lunar tidal currents and changes of level bear approximately this ratio to those caused by the Sun. Thus the Moon dominates the ocean tides (and also the Earth tides). But in the atmosphere the Sun produces daily changes of temperature, and the associated pressure changes much exceed those caused by the tidal action of the Sun and Moon. Thus the Sun dominates the dynamics of the atmosphere. In the tropics the changes of temperature and pressure are more regular than in higher latitudes, and the barometer shows a regular solar semidiurnal pressure variation with an amplitude of about 1 mbar; the maxima occur at about 10 a.m. and 10 p.m. local mean solar time. As we proceed to higher latitudes the regular daily pressure change decreases, and the irregular weather changes of pressure grow, so as to make the regular changes difficult to detect on barographs. But they can still be determined by averaging the records over many days, thus reducing the irregular changes.

The observations are generally made at definite solar hours. The determination of the lunar daily variation, proceeding according to lunar time, can be done in a number of ways. It is desirable to use a method which permits the concurrent determination of both the solar and lunar daily oscillations; such a method was developed by Chapman and Miller<sup>1</sup>.

## The Harmonic Dial

It is convenient to denote by  $S$  a daily periodic change caused by the Sun, and by  $L$  one caused by the Moon. Thus  $S(T)$ ,  $S(p)$ ,  $S(v)$  may denote the solar daily changes

of air temperature  $T$ , pressure  $p$ , and wind velocity  $v$ , and likewise for  $L$ . These changes can be analysed into their harmonic components, of the form

$$s_n \sin(n\tau + \sigma_n)$$

for  $S$ , and

$$l_n \sin(n\tau + \lambda_n)$$

for  $L$ . Here  $t$  denotes solar time expressed in angle at the rate  $15^\circ$  per mean solar hour, and  $\tau$  lunar time at the same angular rate per mean lunar hour. Any such harmonic component can be denoted by  $S_n$  or  $L_n$ .

Fig. 1. Harmonic dial of the lunar barometric tide at Batavia (Djakarta). Each dot represents the determination for one year. The end point  $C$  of  $OC$  is the mean for 40 years. The circle of probable error for the individual yearly determinations is shown with its centre at  $C$ . (Bartels, 1927.)

Solar heating and cooling of the air generally produce one daily maximum of  $T$  and one daily minimum, but the variation is not simply sinusoidal; at night the fall of temperature is slower than the daytime rise to the early afternoon maximum. Thus  $S$  has components,  $S_2$ ,  $S_3$ ,  $S_4$ , . . . of period 12, 8, 6, . . . hours, as well as its main diurnal component  $S_1$ , of period 24 h.

There are associated components  $S_1(p)$ ,  $S_2(p)$ ,  $S_3(p)$ , . . . in the solar daily pressure variation, but their magnitudes

\* Also affiliated with the University of Texas.

† Also of the Geophysical Institute, University of Alaska, College, Alaska.

are not simply proportionate to  $S_1(T)$ ,  $S_2(T)$ ,  $S_3(T)$ . . . . The semidiurnal variation  $S_2(p)$  is magnified by a small degree of resonance in the atmosphere, so that at most places it exceeds  $S_1(p)$ .

The lunar tidal potential has many periodic components; the semidiurnal term  $L_2$  is much the greatest. This is the term that has been most extensively studied in meteorological data. The varying distance of the Moon causes the lunar tidal force to vary, and its mean maximum is 1.37 times its mean minimum. The lunar air tide  $L_2(p)$  has been shown to increase from apogee to perigee in approximately this ratio<sup>3,4</sup>.

Thus  $S_2(p)$  and  $L_2(p)$  are the main solar daily and lunar daily variations of barometric pressure. At Batavia, now called Djakarta, Indonesia, their annual mean values are as follows (in mbars):

$$S_2 = 1.32 \sin(2t + 160^\circ), \quad L_2 = 0.082 \sin(2\tau + 68^\circ)$$

The maxima in these semidiurnal oscillations occur, respectively, at the solar and lunar hours (both a.m. and p.m.),

$$t_{\max} = \frac{90^\circ - \sigma_2}{30}, \quad \tau_{\max} = \frac{90^\circ - \lambda_2}{30}$$

Such oscillations can be conveniently indicated on a polar diagram called a harmonic dial<sup>4</sup>, because in its complete form it resembles a clock face. Fig. 1 is an example; it shows forty points ( $P$ ), each of which specifies the value of  $L_2(p)$  at Djakarta for one of the years 1866–1905. The distance  $OP$  from the dial centre  $O$  to any point  $P$  gives the value of  $L_2$  for that year;  $\lambda_2$  is the angle made by  $OP$  with the right-hand part of the horizontal axis. Regarded as a clock hour-hand  $OP$  also indicates the time  $\tau_m$  of maximum.

The point  $O$  is the centroid of the forty points  $P$ , and  $OC$  represents the 40-year mean value of  $L_2$ . The yearly points  $P$  differ from  $C$  because of the aperiodic barometric changes present even at the low latitude of Djakarta. Their scatter supplies a measure of the accuracy of the mean determination. Bartels<sup>5</sup> showed how to determine a probable error  $e$  for each yearly determination, when the distribution of the points  $P$  around  $C$  is reasonably symmetrical. The circle of "probable error" with radius  $e$  should contain half the points  $P$ , if the scatter is Gaussian. Nineteen of the forty points in Fig. 1 are within the circle of probable error there shown, and therefore the condition is well satisfied for  $L_2(p)$  at Djakarta. The probable error of the mean determination  $L_2$  is  $e \cdot n^{-1/2}$  where  $n$  is the number of individual determinations, in this case 40; thus for the 40 year determination it is 0.0021 mbars. Clearly  $L_2(p)$  at Djakarta is very well determined. No determination is regarded as satisfactory unless the amplitude is at least three times the probable error; for Djakarta the ratio is 39.

### Geographic and Time Variations

The first successful determination of the lunar air tide was made for St. Helena in 1842 by Lefroy<sup>6</sup>, then the director of the magnetic-meteorological observatory for the island, on the basis of 17 months' data (bi-hourly pressure values). For extratropical stations much longer series of data are required, because the tide, like the force which generates it, decreases polewards, and the irregular barometric changes due to the weather become very much larger. The first successful determination of  $L_2$  at an extratropical station, namely Greenwich, was made in 1918 by Chapman<sup>7</sup> from 64 years' data. Only about a third of these data were used for the computation; the most disturbed days were omitted—that is, those with barometric ranges larger than 0.1 in. mercury. The resulting mean lunar daily variation of barometric pressure based on 6,457 days of data with small diurnal range is

shown in Fig. 2, which contains also the harmonic dial representation.

Altogether there are now about eighty-five determinations of the lunar atmospheric tide<sup>8,9</sup>, although not all of them have yet been published. Unfortunately these stations are very unevenly distributed over the globe, as can be seen from Fig. 3. This figure shows the amplitude distribution of the lunar tide by isopleths (or isolines). Each dot indicates a station where the lunar tide has been determined.

The amplitudes are given in microbars (1  $\mu\text{bar}$  = 1 dyne/cm<sup>2</sup> = 0.001 mbar). They decrease from the equator towards both poles, as is to be expected because the force which generates the tide decreases with increasing latitude. But although the lunar tidal force is evenly distributed over the Earth, irregularities are found in the distribution of the lunar tide. Along the Pacific coast of North America the amplitudes are unusually low, presumably because the North American Cordilleras impede the tidal motions<sup>10</sup>. The low amplitude at Buenos Aires calls for an explanation. Over the Indian Ocean there appears to be a region of abnormally high amplitudes, although for lack of data it is not certain that this region of high amplitude really extends from East Africa to the

Fig. 2. The lunar barometric tide at Greenwich. *a*, Full curve: average lunar daily variation in mm mercury (1 mm mercury = 1,333  $\mu\text{bar}$ ), computed from 6,457 days' hourly data, 1854–1917; broken curve: lunar semidiurnal component of the variation. (Chapman, 1918.)  
*b*, Harmonic dial representation.

Western part of the Indonesian Archipelago. Some East African stations show high amplitudes, but others do not.

The phase angle of  $L_2$  is on the average about  $75^\circ$ , so that high tide (maximum barometric pressure) occurs about 30 min after the Moon crosses the local meridian. Individual stations, however, show deviations from this average; the barometric maximum at some stations, notably Greenwich, occurs nearly an hour before lunar transit. At the great majority of stations, however, the maximum occurs after lunar transit; the latest maximum, nearly 2 h later, is found at Haifa-Jerusalem. These phase

that this variation throughout the year, contrary to most annual meteorological variations, has the same phase in both hemispheres; that is, the minimum amplitude and the greatest delay of the barometric maximum after lunar transit occur simultaneously in the northern and southern hemispheres. A few stations do not follow the characteristic pattern shown in Fig. 4, but in most of these the difference between the summer and winter amplitudes and phases is within the limits of the probable errors. There does not seem to be any preponderance of deviating stations in either hemisphere. Thus this annual atmospheric variation has the same phase in both hemispheres.

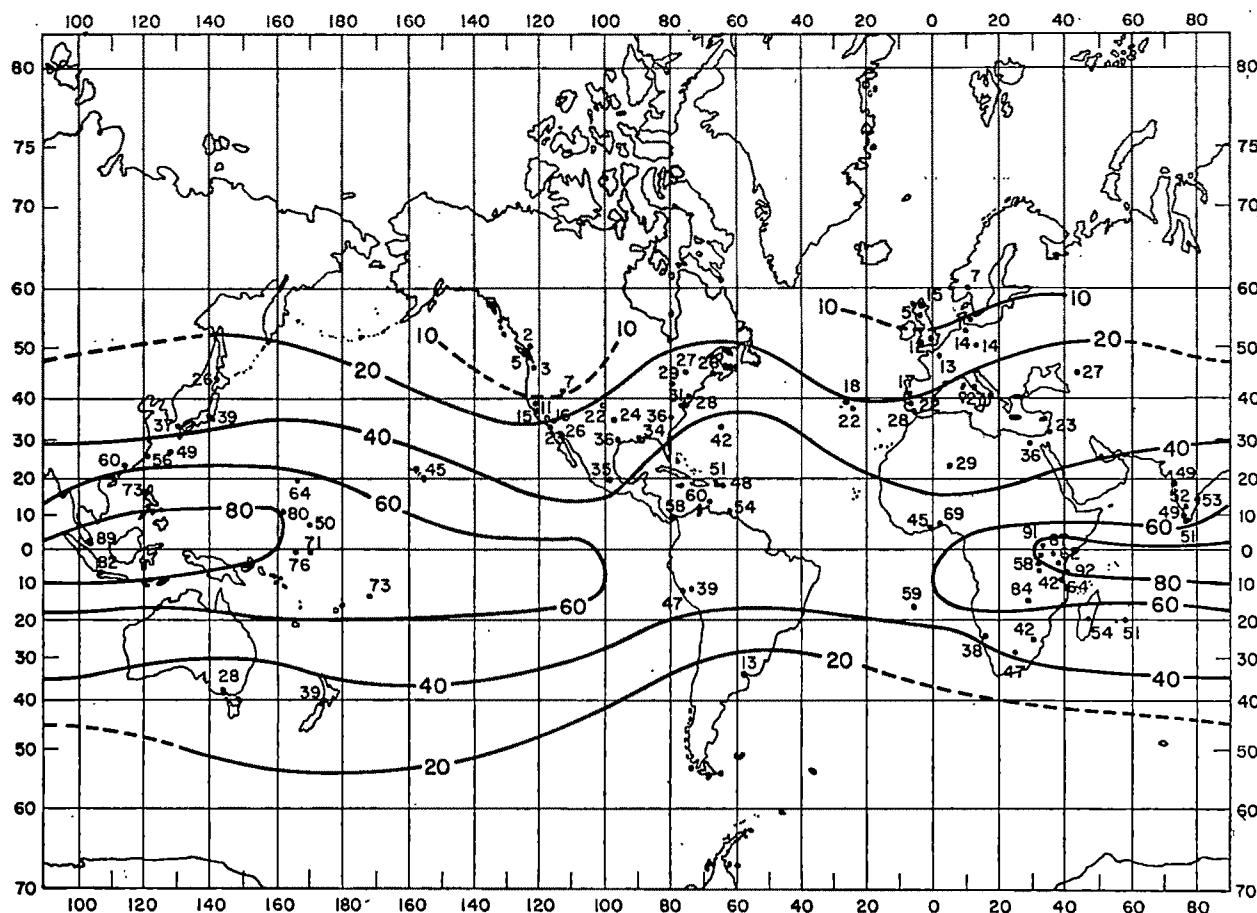

Fig. 3. Global amplitude distribution of the lunar semidiurnal tide (unit  $1 \mu\text{bar} = 10^{-3} \text{ mbar}$ ). The number at each station dot shows the local amplitude of  $L_2(p)$ .

differences may be partly due to errors in the determinations, because of insufficient data. But the larger part of these differences must be real, and their explanation must be sought in the irregular response of the Earth's atmosphere to the tidal force. The reduction of the length of the lunar day by about 10 min from perigee to apogee can clearly not account for these phase differences.

The lunar tide shows a pronounced annual variation, illustrated in Fig. 4, where two Puerto Rican stations are combined<sup>11</sup> to give a more reliable determination. The Roman numerals denote the 12 months; circles of probable error are shown for the odd months. The outstanding characteristics of the annual variation of  $L_2$  are the smaller amplitude and the later maximum during the northern winter months. It is particularly remarkable

### Temperature and Wind

The heating of the Earth's atmosphere by the solar radiation reflected and scattered by the Moon is quite negligible. But the lunar tidal pressure wave produces a lunar semidiurnal temperature wave. Depending on whether the changes of state produced by the pressure wave are isothermal or adiabatic, or follow an intermediate polytropic curve, the magnitude of the resulting changes of temperature and density will differ, as in the case of the Newtonian (isothermal) and Laplacian (adiabatic) calculations of the speed of sound. With the propagation of sound the changes of state are adiabatic, because they are so rapid that the temperature excess due to compression cannot be conducted away. It might be

Fig. 4. Harmonic diurnal of the monthly means of the semidiurnal lunar barometric tide, Puerto Rico. Only every second circle of probable error is plotted. (Haurwitz and Cowley, 1966.)

expected that the tidal oscillations are slow enough to be isothermal. But the distances between regions of high and of low pressure are so great, in most latitudes, that no substantial heat flow can occur in the available time between the locations of greatest expansion and compression. Thus the motion should be adiabatic. This inference was confirmed<sup>12</sup> for Djakarta with the aid of 63 years of bi-hourly temperature data. The lunar temperature wave was found to have an amplitude of  $0.0086^\circ\text{C}$ , with a probable error of  $0.0030^\circ\text{C}$ , while the theoretical amplitude, assuming adiabatic changes, should be  $0.0072^\circ\text{C}$ . The phase constant is within  $2^\circ$  of that expected. It is possible that the atmosphere in contact with the ocean can conduct heat from or to it more readily than is possible at a land station like Djakarta, so that on a small oceanic island the tidal motions may not be adiabatic. A check of this surmise would require analysis of a long series of temperature data on the windward side of a small flat island. It is likely that thermal conduction in the high atmosphere, well above 100 km, is sufficient to make the lunar tidal motions there more nearly isothermal. But no data are yet available to check this.

The lunar air tide, like its oceanic counterpart, has associated tidal currents, and thus should also be apparent in the wind. Like the tidal barometric oscillation, the lunar tidal air motion is very small, with an amplitude of the order of 1 cm/sec. Because of the great variability of the wind, with much larger irregular variations than the lunar tidal amplitudes, scarcely any observational determinations of the lunar tidal wind have yet been made. The only published determination of the lunar tide is for Mauritius<sup>13</sup> ( $20.1^\circ\text{S}$ ,  $57.5^\circ\text{E}$ ) in the Indian Ocean, based on 16 years of data. The expressions found for the southward ( $u$ ) and eastward ( $v$ ) components are

$$u = 1.2 \text{ cm/sec } \sin(30\tau + 176^\circ) \pm 0.6 \text{ cm/sec}$$

$$v = 1.0 \text{ cm/sec } \sin(30\tau + 220^\circ) \pm 0.6 \text{ cm/sec}$$

This determination cannot be considered satisfactory; its probable error is too great. A more recent lunar wind determination for Balboa, Panama ( $9.0^\circ\text{N}$ ,  $79.5^\circ\text{W}$ ), based on somewhat more than 20 years of data, gave the following results:

$$u = 1.2 \text{ cm/sec } \sin(30\tau + 209^\circ) \pm 0.6 \text{ cm/sec}$$

$$v = 0.6 \text{ cm/sec } \sin(30\tau + 195^\circ) \pm 0.8 \text{ cm/sec}$$

This result is still less satisfactory. To reduce the probable error to acceptable proportions more data would be needed—the error decreases as the square root of the number of data. In this connexion it is of interest to note that a pilot study for Balboa based on one year of data (rather than 20 years as here) gave probable errors  $\sqrt{20}$  times larger, as is to be expected from the theory of errors.

#### • High Altitudes

Tidal theory shows that the wind speed due to the tidal oscillation must increase upward nearly in inverse proportion to the square root of the density. Under average conditions the density at 70 km is about one ten-thousandth of its surface value. Thus the speed of the lunar tidal wind should there be about 100 times larger than at the ground. The solar semidiurnal wind oscillations at those levels in fact have amplitudes of some tens of m/sec, compared with surface values of some tens of cm/sec. These solar semidiurnal wind oscillations at high levels have been determined by radio from the drift of meteor trains. These observations have permitted the determination of solar daily wind variations, but they are not numerous enough, as yet, to give the smaller lunar tidal oscillations. Greenhow and Neufeld<sup>14</sup> estimated from their radio meteor observations at Jodrell Bank that the amplitude of the lunar tidal oscillation is no larger than 2 m/sec at levels of about 80 km.

At these altitudes and higher in the ionosphere, additional indication of the lunar tide is obtained from ground based observations of geomagnetic and ionospheric parameters; indeed some of the first lunar daily magnetic variations were discovered only about 10 years after the first successful determination of the lunar barometric tide. The generally accepted explanation of these lunar daily geomagnetic variations, and of the corresponding solar daily geomagnetic variations, is given by the "dynamo theory". This theory attributes them to electric currents flowing in the ionosphere; which are induced by the mainly horizontal oscillatory motions, tidal and thermal, of the ionospheric air. The process resembles that in a dynamo: the moving air corresponds to the armature, the conducting ionospheric layers to the armature winding, and the geomagnetic field to the magnetic field of the dynamo electromagnet. From the current the type of the inducing air motion at these levels can be inferred, but to determine the speed requires a knowledge of the electric conductivity of the layers in which the current flows. Matsushita<sup>15</sup> from recent data on the lunar daily geomagnetic variations gave the following estimates of the required wind system ( $\theta$  = colatitude):

$$u = 1.7 \text{ m/sec } \sin\theta \cos\theta \sin(30\tau + 60^\circ)$$

$$v = 1.7 \text{ m/sec } \sin\theta \sin(30\tau + 150^\circ)$$

These amplitudes are more than a hundred times larger than those observed (and expected) in lunar tidal winds at the surface. As already explained, such an increase in strength with elevation is to be expected for this type of wave motion. The phase constant of the southward wind component  $u$  should be  $90^\circ$  larger, that of the eastward component  $v$  should be  $180^\circ$  larger, than the phase constant for the pressure oscillation. The surface pressure oscillation has a phase constant of about  $75^\circ$ , and Matsushita's wind determination from geomagnetic data would require for the lunar pressure variation aloft a phase constant of  $330^\circ$ . On the other hand, J. H. Chapman<sup>16</sup> has determined lunar tidal drifts in the  $E$  layer with amplitudes about ten times larger than those obtained by Matsushita. The phase constant of his determination agrees well with the theoretically expected values for both components, if it is assumed that the phase constant for the pressure variation is the same at the ground and in the  $E$  layer. Despite this consistency, the disagreement between these results and those of Matsushita and

Greenhow and Neufeld indicates that our knowledge of the lunar tide in the higher atmosphere is still very incomplete. Numerous data are available on the variation of geomagnetic and ionospheric parameters with lunar time<sup>15</sup>, but in most cases the interpretation of these data in terms of atmospheric motions, both horizontal and vertical, is still obscure.

Reliable lunar tidal variations of cosmic rays<sup>17</sup> have been found, mainly in the number of mesons received at the ground. From these measurements it has been inferred that the lunar tide at an elevation of about 18 km, where the mesons are generated by primary rays, is about ten times greater compared with the surface tide. Lunar variations have also been looked for and reported in other atmospheric parameters, such as the intensity of the oxygen green line 5577Å of the airglow<sup>18,19</sup>, the twilight intensity<sup>20</sup>, the polarization of sky light<sup>21</sup>, the rainfall<sup>22</sup>, the content of ozone in the atmosphere<sup>23</sup>, and the rate of meteors entering the Earth's atmosphere<sup>24</sup>. But the statistical basis of these relations is weak, and the physical connexions, if they do exist, are not clear. At least some of these relations, if they do prove to be real, may be semimonthly or monthly, not semidiurnal.

### Origin of Tides

According to the "equilibrium theory" of the tides, which ignores inertial effects, the amplitude of  $L_2$  at the equator should be 34  $\mu$ bar. As Fig. 3 shows, the amplitude is actually about 2.5 times larger. This is because the atmosphere requires a finite time to adjust to the changing tide generating force of the Moon. The result is a slight resonance magnification of the computed equilibrium tide, as observed. In order to determine the lunar tides to be expected from theory, the hydrodynamic equations of motion and continuity have to be used, together with a physical equation relating the pressure and density changes of the air<sup>25</sup>. For this equation it is generally assumed that the relation is adiabatic, and this assumption appears to be confirmed by the lunar tidal variation of temperature at Djakarta. The calculation shows that the surface pressure variation due to the lunar tidal force agrees reasonably well with what is to be theoretically expected. The actual amplitude and phase depend on the assumed vertical structure of the atmosphere. This was in particular shown by Sawada<sup>26</sup>, who computed them for various atmospheric models with different temperature distributions above the troposphere.

While there is thus no difficulty in accounting for the general distribution and magnitude of the observed lunar tidal oscillation, the irregularities of its distribution over the Earth, and the pronounced seasonal variation, require explanation. The lunar tidal potential is distributed quite regularly over the Earth; thus the irregularities in the barometric lunar tide must be due to the response of the atmosphere to the exciting force. One possible disturbing cause may be the ocean tide. Atmospheric tidal theory assumes in general that the Earth's surface is both horizontal and rigid; this is clearly not correct for the approximately 70 per cent of the Earth covered by water, which is subjected to tidal influences. Because of the irregular distribution of land and water this effect must be quite complex. (There will also be a smaller effect because of the solid-earth tide.) Sawada<sup>27</sup> has studied the effect of the ocean tide on the atmospheric tide, but only for an ocean completely covering the Earth. He found that such an ocean can indeed very appreciably affect the atmospheric tide, especially its amplitude. But more work is required to determine the effect of tides in oceans of limited extent, and to see whether it is in the right direction to explain the observed anomalies. Wulf and Nicholson<sup>28</sup> had earlier attempted a qualitative explanation of the geographical irregularities of  $L_2$  and its remarkable annual variation, stressing specifically the much greater and more widespread surface irregularities over the northern than over the southern hemisphere.

Sawada<sup>29</sup> has studied whether the effect of a zonal motion of the atmosphere, heretofore neglected in the theory of the lunar tide, would explain this peculiar annual variation. He showed that appropriate seasonal changes in the zonal wind distribution, especially its vertical shear, would account for the annual variation of  $L_2$ . This effect depends very much on the zonal wind distribution in both hemispheres. Unfortunately the wind distribution in the southern hemisphere is not yet sufficiently well known to decide whether this explanation of the annual variation of  $L_2$  is satisfactory. In any event the meridional temperature gradient associated with the zonal wind system has less influence on the annual variation than the winds themselves. But an annual variation of the mean global vertical temperature distribution could also give rise to the observed annual variation of  $L_2$ . The solution of this problem and of many others concerning the lunar tide lies in the future.

In *Nature* (101, 359; 1918) there appears the following abstract of the proceedings of the Royal Meteorological Society—"Dr. S. Chapman: The lunar atmospheric tide at Greenwich, 1854-1917. The tidal forces due to the moon affect the aerial as well as the fluid ocean, and the lunar atmospheric tide is manifested by the periodic variation in the height of the barometer having two maxima and two minima (high and low tide) in the course of a lunar day. This variation is much smaller than the solar semidiurnal barometric variation, which is not a simple solar tidal effect; the minute lunar variation, however, can be detected with ease in the records of tropical observatories, where the irregular fluctuations of pressure are small. Attempts to determine it in the records of European observatories have been made, but hitherto without success. By treating hourly observations of 'quiet' days only, on which the barometric range did not exceed 0.1 in., and by abstracting the solar variation, the lunar atmospheric tide at Greenwich has now been ascertained. Its total amplitude is less than 0.001 in., the harmonic formula being  $0.00036 \sin(2t + 114^\circ)$  in., where  $t$  represents lunar time measured, at the rate of 360° per lunar day, from the epoch of upper transit. A comparison with the variation at Batavia (lat. 6° S.), viz.  $0.00256 \sin(2t + 65^\circ)$  in., suggests that the amplitude varies as the fourth power of the cosine of latitude, and that the phase also varies with latitude."

## BOOK REVIEWS

### STRUCTURAL ANTHROPOLOGY

#### *The Savage Mind*

By Claude Lévi-Strauss. (The Nature of Human Society Series.) Pp. xii+290. (London: Weidenfeld and Nicolson, 1966.) 45s. net.

WHEN the speculative, theoretical and comparative approach of the evolutionist school of anthropology fell into disrepute, it yielded to studies of single societies based on intensive field research. During the past half century a body of essential basic knowledge of societies and their cultures has been built up in a series of monographs, but the theoretical and comparative use made of this material has been relatively slight. Now, once again, there is a return to the comparative approach, but it is a return with a difference. In involves the search for consistencies of structures, functions and meanings through analysis in depth, making use of the findings of field research and in turn inspiring more detailed field studies.

In the forefront of this return to comparative anthropology is its chief inspirer, Professor Lévi-Strauss, who is both an ethnologist and a philosopher. *The Savage Mind*, first published in French under the title *La Pensée Sauvage* (1962), is an important landmark in the development of modern anthropological thought and might be said to have inaugurated the new era.

Already this book has brought about a profound change in attitude towards the philosophical systems and classifications of peoples throughout the world. Only a few years ago the primitive, intellectual level of thought was assumed to be as low as the technological and economic level. Primitive people in general lacked words for abstracts and did not think in general categories, only in concrete, particularistic terms—so it was asserted. When the occasional field worker produced evidence to the contrary both the field material and the conclusions were frequently doubted. This book once and for all destroys these assumptions, revealing their essential naivety by reviewing the wealth of primitive systems of thought and belief in many cultures, the ways of classifying the natural world and integrating this world with society and culture. Analytical reasoning, Lévi-Strauss shows, occupies a considerable place in all societies, primitive and complex alike. After reading this book no one can ignore the possibility of finding in his field of study elaborate classifications of categories, elements, species and numbers, of encountering a wealth of knowledge relating to natural life with complex classifications used in order to conceptualize society and culture. There is now no excuse for failing to make a deliberate investigation into these possibilities and their social significance.

The two major systems which are used as examples are totemic classifications and caste. The approach Lévi-Strauss uses is, in both cases, essentially a structural one. On one hand, the diversity of species in nature and on the other the diversity of functions on a cultural plane have furnished man with models of social classification and structure. The function of each is succinctly stated; totemic groups exchange women, castes exchange goods and services. Both are a means of securing or displaying the interlocking of social groups with one another.

Totemism is only a particular case of a general problem of classification, one of the many examples of the role which specific terms often play in the working out of a social classification (page 62). Names are discussed as

another mode, the prohibition on using the names of the dead being expressed as a structural property of certain systems of naming. The couvade, games and myths are other important subjects which are covered. This structural approach, not only to ritual forms but also to their religious and magical content, is particularly interesting since beliefs had not hitherto seemed to lend themselves to structural analysis in the way that institutions and general social organization have done.

The steps by which Lévi-Strauss reaches his conclusions are frequently complex and open to argument. His style of expression, moreover, is often turgid. Nevertheless, in spite of the disagreements and disputes which will rage around many of the author's assertions—for his approach is always a challenging one—his postulates invariably possess the virtue of that inspiration which produces creative thought. In the structural school of anthropology, of which he is the leading theoretician and proponent, we may disagree with Lévi-Strauss; we cannot afford to ignore his work which, when pondered over, increasingly illuminates the interpretation of social systems.

AUDREY J. BUTT

### MEMORY

#### *Aspects of Learning and Memory*

Edited by Derek Richter. Pp. x+182. (London: William Heinemann Medical Books, Ltd., 1966.) 35s. net.

THIS book contains eight chapters, by various authors, and are largely independent of each other. They are all concerned, in one way or another, with experimental evidence bearing on the problem of memory and learning. These range from a discussion of human psychology (M. Metcalfe) and of the effects of human brain damage (W. R. Russell, F. Newcombe and J. H. Brierley) through a discussion of learning in animals (I. S. Russell) and its possible neurological basis (J. H. Gaddum and B. S. Meldrum), to biochemical aspects of the problem (D. Richter). As will be apparent from this list of topics, the coverage is wide and the book draws the reader's attention to most relevant lines of research. The references are extensive and well chosen and the book is, on the whole, well written.

On the rare occasions where anything of an arithmetical nature is discussed, however, it is usually wrong or misleading. J. H. Gaddum (page 54) discusses the total number of possible patterns of instantaneous activity for the nerve cells in the brain and obtains the number  $2^{100}$ , rather than  $2^{10^6}$ , which is very different. His use of the word "pattern" is muddled and inconsistent—a pattern cannot at the same time cover all nerve cells and be spreading (pages 67–68). D. Richter's calculation of  $10^{130}$  patterns of synaptic modification (page 94) is based on such a special assumption that it seems quite pointless. It is wrong, anyway, to be very impressed by the size of numbers like  $2^{100}$ ; the information content of a choice from one of  $2^{100}$  is only 100 bits, while that of a choice from  $2^{10^6}$  is  $10^6$ , which is probably comparable with the human memory capacity (see, for example, page 91). On a different topic, I. S. Russell (page 164) states that Wilson, Oscar and Bitterman found matching in probability learning in the monkey and that this was because the monkey adopted the strategy of avoiding the previously rewarded alternative. This strategy would lead to anti-matching; the actual behaviour was more complex, the data sparse and I incline to think the matching observed was partly fortuitous.

I. S. Russell has marred an otherwise interesting chapter by a lot of loose talk about "data processing", "encoding", etc. Many biologists nowadays love using words of this sort, but it seems to me usually both pointless and undesirable. To those who are familiar with the words in their normal contexts, there are overtones which are by

no means necessarily correct in the biological situation and therefore the words are probably misleading at least. An example of positive error is the assertion on page 153 that retrograde amnesia in man shows that a certain period of time is required for memory to be encoded. As a distinction is made (page 156) between "encoding" and "storage", that assertion is clearly untrue.

There is a centrally important matter about which definite statements are made, but for which I think there is no solid evidence one way or the other. J. H. Gaddum (page 61) states that "most neurones in the brain of an animal are continuously active while the animal is awake" and B. S. Meldrum (page 118) that "every time a stimulus is received and a learned response made, most of the cells of the brain are involved". These statements may well be true, but I do not think we can be sure. Also one might usefully note the apparent inconsistency of the specific proposal (I. S. Russell, page 159) of the relevance of the hippocampal-fornix system for memory with the very interesting observation (J. H. Brierley, pages 34, 37) that bilateral section of the fornix has no apparent effect on memory.

The extent of criticism in this review is much more a reflexion of my own interest in the subject than of wholesale defects in the book. I can recommend it as a clear and, on the whole, well written and accurate survey of a large part of the field. In particular it is a pleasure to see that none of the authors has that uncritical approval of the RNA hypothesis about memory which we have seen so much of in recent years.

J. S. GRIFFITH

## NEMATODES

### Nematodes

By H. D. Crofton. (Hutchinson University Library.) Pp. 160. (London: Hutchinson and Co. (Publishers), Ltd., 1966.) 32s. 6d. hardcase; 13s. 6d. paperback.

NEMATODES may be unpopular with many students because some teachers cling to the absurd belief that the study of parasites is not quite respectable. Nevertheless, research on free living nematodes as well as forms which parasitize plants, animals and man has created the formidable subject known as nematology. These round worms originated in the sea and more than half the existing nematode species are still marine, less than a sixth living in fresh waters and soils, less than a quarter living parasitic lives. In spite of notable structural uniformity over an immense range of sizes, nematodes follow various modes of life and display versatility in the patterns of their life histories. The turgid body is covered by a complex proteinaceous cuticle. The muscles of the body wall act in conjunction with a pseudocoelomic hydrostatic skeleton to control form and play some part in locomotion. This unique turgor-pressure system is related to modified bodily functions: a muscular pharynx is needed to force liquid food into a collapsed intestine; defecation requires special muscles and reproduction special mechanisms—to inject non-flagellate sperms under pressure at copulation and to transport oocytes and eggs along the ducts of the female system. Functional simplicity is often more apparent than real; metabolic processes change according to conditions which may vary in the same habitat, and the basic life cycle with its five stages of growth and development and four intervening moults may be modified to fit in with special problems of parasitic life.

In dealing with general organization, the structure of the body wall and somatic musculature, various organ systems, embryology and development, metabolism, patterns of life history and the characters and features of the free-living and parasitic types of Nematoda, Dr. Crofton has condensed and dispensed a large amount of information and many interesting ideas which indicate

the directions of future progress within a very small space. He has given also an outline scheme of classification and a list of references, which could be enlarged with benefit in later editions. Many students and teachers of zoology will be grateful for this concise account of a group of animals which has very great economic and medical importance in the modern world and a much greater interest for many of us than some teachers believe.

The paperback edition will be a "must" for all students with an eye for good value.

BEN DAWES

## THE COMPLEAT RUMEN

### The Rumen and Its Microbes

By Robert E. Hungate. Pp. x+533. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1966.) 158s.

ACKNOWLEDGED as one of the most distinguished investigators in the field of rumen biology, Professor Hungate has drawn together the results of his own considerable research and those of other workers into a comprehensive and scholarly account of rumen ecology. The result is an outstanding contribution to our knowledge of microbe-ruminant symbiosis.

The book falls naturally into two sections. The first is concerned with the fundamentals of rumen biology and includes descriptions of the microbial populations and their activities, both from qualitative and quantitative points of view. Consideration is given to autecological studies of the various micro-organisms, but the author emphasizes that the microbial populations are interrelated in too many ways to allow simple interpretations of their symbiotic relationship to the ruminant. The diversity of microbes and the complexity of metabolism in the rumen are related clearly to the chemical heterogeneity of the plant diet. In this context the concept of maximum biochemical work is developed: of the various possible carbohydrate fermentation pathways, certain combinations effect greater cell yields than do others. Consequently, maximum growth necessitates a complex microbial population possessing many more pathways for biochemical work than are present in a single species. The author argues that carbon dioxide, methane, acetate, propionate and butyrate are the major fermentation products in the rumen because the anaerobic routes leading to them provide the most efficient conversion of substrates into microbial cells. This concept goes a long way in rationalizing the diversity of the rumen microbiota.

One of the most interesting expositions in this book is devoted to the kinetics of ruminant digestion and its approximation to continuous fermentation systems, an approximation which becomes remarkably close when animals are fed at frequent regular intervals. Increasing turnover rates in the rumen produce greater host yields but, as in continuous culture systems, increases in rate beyond the point at which microbial reproduction can maintain a constant population result in washing out. This discussion is not a restricted academic one; the reader's attention is directed to the importance of rumen turnover and to resultant feeding practices that are significant in ruminant economy.

The second part of the book evaluates the applied aspects of rumen ecology and covers such areas as ruminant metabolism, rumen variations, practical applications and abnormal rumen functionings. Here, too, are considered such factors as feed additives, including enzymes and antibiotics, and rumen inoculation. Throughout the discourse is made complete by reference to the techniques of rumenology—cultivation of micro-organisms, methods of sampling, estimation of feed digestibility and nutritional status of diets, to mention but a few examples.

A measure of Professor Hungate's success is unmistakable in the authoritative way in which he deals with the

multifarious aspects of his subject, whether he is considering the neuromuscular control of stomach movements or the physiology of cellulolytic bacteria. The book is well illustrated and the proof reading has been assiduous. The only detraction would appear to be its very high price.

ALAN T. BULL

## MUTUAL BENEFIT

### Symbiosis

Vol. 1: Associations of Micro-organisms, Plants, and Marine Organisms. Edited by Henry S. Mark. Pp. xviii + 478. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1966.) 132s.

THE original definition proposed by De Bary in 1879 states that symbiosis is a constant and intimate association between dissimilar organisms. Such a definition covers all forms of parasitism as well as mutualism and commensalism. Many modern workers prefer to restrict to symbiosis only those associations in which mutual benefit is involved. In electing to review the subject of symbiosis in the wide sense of the word, leaving out only the less relevant aspects of parasitism, Mark has taken on a very difficult task. The result is, however, in Volume 1, an excellent comprehensive review of a very wide range of associations involving micro-organisms, plants and marine animals.

Chapter 1, which deals with symbioses involving only micro-organisms, is particularly valuable, because this aspect of the subject is not well documented in review form in the literature. The next four chapters deal respectively with lichens, bacterial symbioses with plants, mycorrhizas and endozoic algae. Chapters 6 and 7 deal with symbioses involving marine animals, and Chapter 8 is concerned with methods for the experimental analysis of behaviour in symbiosis.

This volume will prove very valuable in highlighting similarities between apparently very different associations. Perhaps more important, it will indicate similar methods for experimental investigation of these associations. The review will be welcomed by all biologists working on problems of symbiosis.

B. W. FERRY

## NEUROSCIENCE IN JAPAN

### Correlative Neurosciences

Part B: Clinical Studies. Edited by T. Tokizaire and J. P. Schadé. (Progress in Brain Research, Vol. 21B.) Pp. xi + 437. (Amsterdam, London and New York: Elsevier Publishing Company, 1966.) 145s.

THE books in this series are always beautifully produced and often contain work of major importance. This is the second part of a work dealing with clinical neurological studies and the relationship of neuro-anatomy, neuro-physiology and neuro-chemistry to the clinical sciences. This is work entirely from Japan and for this reason alone it is of considerable interest. Of the sixteen papers only eight have any direct relationship to clinical subjects. There is a detailed description of the effects of hemispherectomy in ten patients which is beautifully illustrated and makes an important contribution to neurological science. The conclusions about thalamic participation in sensation in these cases are of considerable interest and illustrate how such clinical investigations can enrich the basic sciences.

There is a paper on an extensive epidemiological and clinico-pathological study of cerebral haemorrhage and cerebral-arterial disease in a small Japanese town. It could well serve as a model for similar investigations in this country. Another well documented and interesting survey is on multiple sclerosis in Japan.

One of the most important papers in the volume has already been published elsewhere. This is "Sedative Stereencephalotomy", which marks one of the first incursions into the human hypothalamus. A number of the papers appear to have little connexion with any practical clinical work, but there are three interesting and important papers on sleep.

It would have been interesting to see an account of Forel *H*-tomy in the treatment of epilepsy or, indeed, any of the significant contributions made by Japanese workers in the surgical treatment of dysrhythmia. Instead there is a scholarly account of the human triangular tract of Helweg.

This volume is representative of the considerable neuro-scientific work proceeding in Japan, and makes available material normally inaccessible in Britain.

EDWARD HITCHCOCK

## DOWN'S ANOMALY

### Down's Anomaly

By L. S. Penrose and G. F. Smith. Pp. vii + 218. (London: J. and A. Churchill, Ltd., 1966.) 42s.

THIS book about Down's anomaly (mongolism) covers a field of wide importance and implications to human biology, which transcends what could be considered the rather narrow boundaries of the study of mental deficiency. It makes its timely appearance on the hundredth anniversary of Langdon Down's celebrated description of "mongolian idiocy" and seven years after the recognition of the autosomal trisomy that is the cause of the clinical syndrome. The authors are clearly at home with the subject, and the fact that the senior author has for years given a great deal of original and stimulating thought and research energy to the subject of this book is amply revealed in its outstanding excellence and clarity and thought-provoking quality. After a sweeping historical introduction, which outlines the stages of the characterization of the disorder, the authors review physical signs, devoting special attention to the facial characteristics, including those of ears and eyes, and to those of hands and feet. Various aspects of the intellectual development of the affected person are given prominence, while the limitations of the formal I.Q. studies are critically examined, and the more modern but as yet scanty studies done with methods devised to test specific neural faculties are stressed. Social maturity, which is advanced in these patients, and their personality traits and developmental patterns are given due consideration in the light of their importance to adaptation of the patient and his integration into the community. A chapter is devoted to the distinctive dermatoglyphics found in Down's syndrome and a section of this considers the effects of somatic chromosome mosaicism on the sensitive dermal patterns.

There is a chapter on the haematological changes, in which the increased incidence of acute childhood leukaemia is emphasized, and one on the biochemistry of Down's anomaly which reviews the older work and stresses the more recent descriptions of serum and cell-enzyme changes and of metabolic alterations and their relationship to the trisomic state. The clinical diagnosis of Down's syndrome, the discriminative value of single traits, both metrical and qualitative, and of combinations of characters are given prominence, also because these elements are essential to a proper interpretation of the chromosomal findings in the light of the phenotype, particularly in doubtful cases with mosaicism or with so-called partial trisomy. Thirty pages are devoted to the description of the cytological findings. Standard (or primary) trisomy and the identity of the specific autosome, usually defined as number 21, are considered. Next the centric-fusion type of interchange involving a number 21 and a member of the 13-15 or 21-22 groups, or long-arm isochromosome

formation, are discussed, together with their origins and transmission, in some instances by asymptomatic balanced carrier parents. Chromosome mosaicism and the occurrence of double trisomy, for example for number 21 and XXY, are considered in detail. There follow a chapter on vital statistics in which mean survival age (about ten years or so in some statistics), causes of death and secular changes are discussed, and one on the aetiology of the anomaly. Here the different possible causes of Down's syndrome independent of maternal age are detailed and ideas are put forward about possible factors in the origin of the maternal-age dependent trisomy. Treatment and prevention, for example, by limiting conceptions after a certain maternal age, are considered. The genetic prognosis for those families in which an affected child is born is discussed, and the importance of chromosome studies of the patient and, if necessary, of the parents is emphasized.

The authors of this admirable book express the hope that their way of presenting the material may not only show the advances made but also stimulate further work. They cannot fail to succeed, because they have already achieved their aim of getting at least one reader both interested and stimulated.

P. E. POLANI

## BIOLOGY AND STATISTICS

### Biostatistics

By Alvin E. Lewis. Pp. xi + 227. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1966.) 68s.

THIS is an elementary and essentially non-mathematical exposition of statistical ideas and methods, illustrated with examples mainly from biological sources; it is intended for "students in biology and medicine who have reached the stage where they are ready to judge data and to begin their own investigations and experiments". The standard topics of probability, random sampling, the normal distribution, the chi-squared distribution, tests of significance, and the analysis of variance are all presented, and there are brief chapters on quality control, sequential analysis and distribution-free methods. There is a summary and a good set of examples at the end of each chapter, and an excellent appendix of statistical tables.

It is extremely difficult to write a good statistical text with such a scope and aim, and Dr. Lewis only partially succeeds. Many of his approaches are good, such as the introduction of the *t*-test for paired observations before that for two separate samples. Others are less satisfactory, such as introducing the analysis of variance by way of the variance ratio test; this may mislead the beginner into regarding it as a method for studying heterogeneity of variances when the aim is to study heterogeneity of means. Some of the examples are a little strained ("spherical seeds") and at times the author gives the impression of not being quite at home either with biology or statistics.

IAN SUTHERLAND

## ORIENTATION. STATISTICS

### Structural Diagrams

By Andrew B. Vistelius. Translated by R. Baker. Translation edited by N. L. Johnson and F. C. Phillips. Pp. xi + 178. (London and New York: Pergamon Press, 1966.) 80s. net.

THIS book was originally published in 1958, and deals with the treatment of orientation data from structural geology and petro-fabrics. These data are usually too complex to be tested statistically by the methods used by palaeomagnetists; and although tests have been proposed,

none has been accepted for general use by structural geologists.

In such tests, including those of Vistelius, the results are plotted on a two-dimensional projection. Vistelius rejects the use of equal-angle and the equal-area projections in favour of an equal-interval projection. His arguments are not convincing and his choice increases the labour of testing. He warns against the use of polar instead of equatorial versions of projections, although they give identical plots of data. An introduction to probability theory and statistics is provided, but it is difficult to follow because too much statistical jargon is used in an attempt to be rigorous, and symbols change their meaning from equation to equation and even within paragraphs. Some of the tests proposed before 1958 are critically reviewed.

Vistelius then proposes four new tests which all involve determining the numbers of poles (data) falling in each of the cells of a net laid over the two-dimensional projection of the data. The  $\chi^2$  and normal distributions are used to test for significant differences between the frequency distributions representing diagrams under test, and frequency distributions representing model random diagrams or other real diagrams. The tests include various objectionable features. The nets of cells are tailored to fit the data, which makes the tests partially subjective. The first test uses a false model of random distribution. The cells are so large that they tend to smooth out or randomize the data, thus decreasing the chance of detecting weak preferred orientations; yet the detection of weak preferred orientations is the most important task these tests can perform. Nevertheless, the second and fourth tests given by Vistelius are novel and could be useful if improved.

The book is poorly translated and badly edited. Typographical errors include "n" in place of "m" in Table A14 and a mis-reference to an equation (page 45). Errors arising from a failure to understand the subject are more common and give rise to meaningless and even self-contradictory sentences. Such errors include the literal translation of obscure Russian sentences; unjustified changes in the original punctuation; the omission of "not" in one sentence; and inversion of a mathematical substitution on page 44. Mis-translations include "position" instead of "attitude", and "fissure" instead of "joint". "Exposure", "cell", "thin section", and "cut" in "cut effect" are all translated as "section", causing considerable confusion. Equations 2-13 and 2-20 have been changed from the original without appropriate changes being made in the text.

The book is concerned solely with the statistical testing of diagrams. There is no discussion of sampling methods and neither discussion nor interpretation of the patterns of preferred orientation is shown by structural diagrams.

DEREK FLINN

## OPTICAL ANALYSIS

### Treatise on Analytical Chemistry

Edited by I. M. Kolthoff and Philip J. Elving, with the assistance of Ernest B. Sandell. Part I: Theory and Practice, Vol. 6. Pp. xxiii + 3347-4246. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, 1965.) 175s.

THIS book deals with optical methods of analysis. The ten chapters cover a wide field, from emission spectroscopy to electron microscopy, and from flame photometry to neutron absorption.

A scientific critique of such a wide range of disciplines is clearly beyond the scope of a single reviewer; more is to be gained by taking the position of an interested reader seeking guidance. A random spot-checking within the various chapters for information on specific items gave me

a most favourable impression. The authors of individual sections have achieved a satisfactory balance between the encyclopaedic and the critical and they have together produced a creditable exposition of dispassionate scholarship. The "mainstream" analytical chemist will welcome particularly the chapters on microscopy and refractometry where a hitherto scattered literature has been collected into a unified whole with an analytical emphasis.

With several of the techniques discussed the problem is not complete when a result is read from the instrument; representation, storage and retrieval of information are becoming increasingly pressing problems, and the authors have rightly considered these in fair detail.

Weaknesses can inevitably be found in a work of such dimensions. For example, Chapter 1 on emission spectroscopy lists 185 selected literature references, yet line broadening is discussed without reference to the literature and hollow cathode sources are described without reference to design considerations. These are, however, minor shortcomings in a volume notable for clarity of layout and excellence of literary presentation.

The firm editorial hand is evident throughout in the maintenance of overall balance and adequate cross-referencing between this and other volumes in the series. This volume more than maintains the high standard set by earlier ones in the series and is encouraging testimony to the worthwhile nature of the daunting task which the editors have undertaken.

J. K. FOREMAN

## FRESH IDEAS IN SOLID STATE THEORY

### Many Body Theory

Edited by Ryogo Kubo. (1965 Tokyo Summer Lectures in Theoretical Physics, Part 1.) Pp. iv+160. (Tokyo: Syokabo; New York: W. A. Benjamin, Inc., 1966.) \$7.45.

THIS book contains ten of the more important contributions to the 1965 Tokyo Summer Lectures in Theoretical Physics. It is to the credit of Professor Kubo, the editor, that it escapes the scrappiness and lack of cohesion which can result when isolated papers are detached from the coherent background of cross-questioning and informal discussion against which they were originally presented.

The contributions form a well-balanced selection, though the authors do not always attack their subject on the same level: H. Mori's article on "Relaxation Phenomena near the Critical Points" requires careful study, while D. Pines's "Elementary Excitations in a Homogeneous Base Liquid" is more intuitive, although it ends with some interesting speculations on the occurrence of zero sound. Between these extremes lies a wide spectrum of different approaches, but they have this in common: the authors are concerned with physically relevant ideas, and for the most part include only enough mathematical formalism to clothe them respectably. Nevertheless, the mathematics makes no concessions to the unsophisticated, and heavy reliance is placed on diagrams.

The presentation is consistently clear, and the many misprints are not, on the whole, obtrusive. J. M. Luttinger's "A New Mechanism for Superconductivity" is, however, mathematically cryptic, and the elision of definite and indefinite articles, common in "Japanese" English but rare elsewhere in this book, is an unnecessary barrier to comprehension.

Apart from those already mentioned, the authors include K. A. Brueckner, W. Kohn, J. R. Schrieffer and P. G. de Gennes. To the solid state theorist these are names to conjure with, and they do not disappoint here: Brueckner's articles on "Liquid Helium-Three", "Nuclear Structure" and "Correlated Crystals" are lucid and com-

prehensive, while Schrieffer studies the quasi-particle approximation in normal and superconducting metals, using Migdal's simplification of the electron-phonon vertex function to obtain explicit expressions for the electron self-energy valid to all orders in the electron-phonon coupling strength. W. Kohn, summarizing his own work on the subject, formulates the problem of the inhomogeneous electron gas in terms of a functional  $F[n(r)]$  characterizing the ground state, while de Gennes discusses Landau-Ginsburg theory and Type II superconductors.

In short, ideas abound in this lively volume; many of them need the firm anchorage of further work, but this is not in the nature of a criticism. I recommend the book both to graduate students and to more senior workers who are seeking inspiration suitably leavened with information.

A. E. K. DOWSON

## NMR THEORY

### The Theory of Nuclear Magnetic Resonance

By Igor Vladimirovich Aleksandrov. Translated by Scripta Technica, Inc. Translation edited by Charles P. Poole, jun. Pp. x+197. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1966.) 70s.

THIS book is a translation of the original Russian version which was published in 1964. In view of its title and contents, it immediately invites comparison with the classic and authoritative book by Abragam which was published in 1961. Incidentally, it is surprising to find no reference to Abragam's book in this. The comparison is not favourable to Aleksandrov, for his book gives an impression of a laboured and pedestrian approach, in spite of some quite elegant mathematics, and one feels that the author experienced no joy in his work. The field is one capable of more exciting and yet sound presentation, as has been shown by Abragam, Slichter and Pople.

The book presents the basic theories of magnetic resonance relaxation, a few topics in the theory of line shapes in solids, the theory of the chemical shift and the indirect spin-spin coupling in molecules, and in a final chapter a hotchpotch of minor problems in nuclear magnetic resonance. This presentation is in quite a logical order but does not achieve the unity required of a book, and this is emphasized by the different notation used in reporting the theories of Kubo and Tomita, Bloch and Redfield. While this is helpful to persons familiar with their notations, and it is no doubt deliberate, it makes it very difficult to compare the several theories. No real and searching comparison of the differences and relative advantages of the theories is presented, which is unfortunate because many experts in the field would be glad to see this discussed.

The discussion of the difficult and complex matter of the chemical shifts and  $J$  couplings is thorough, but I suspect that it may by now be rather out of date in view of the great interest in this field. It is remarkable that here, as indeed throughout the book, virtually no experimental results are quoted. They are unusually lacking even for an avowedly theoretical treatment and they are certainly necessary in the molecular theory which is notorious in its disagreement with experiment.

The translation is not convincing and the editing is not thorough. There are words not to be found in English or improperly used (kinetical, nontrivial, nonzero, etc.), a number of misleading mathematical errors ( $t-t_0-i\hbar\lambda$  for  $t_0-t-i\hbar\lambda$ , errors of sign, omission of symbols, etc.), and a large number of printer's errors (Poole for Pople, both  $T_r$  and  $S_p$  used, etc.). The price is on the high side. A useful reference book but no more.

J. G. POWLES

## USES OF ISOTOPES

**Les Radioéléments, Facteurs de Progrès Economique**  
Par Albert Nils. Pp. xii+214. (Paris: Dunod, 1966.)  
32 francs.

As an introduction the reader gets eight pages of very elementary explanations about the nucleus, the atom, artificial radioactivity and the production of artificially produced radioisotopes, written for a man with some basic knowledge of chemistry but not necessarily of physics.

The second chapter "Nuclear Energy and Radioisotopes" deals in a very succinct way with the present demand and resources of energy. The figures given in this chapter might be slightly out of date. The main part of the book is a summary of other publications on the advantages—mainly the financial ones—of using radioisotopes in industry, but also in medicine and agriculture.

It must be admitted that it is very difficult to undertake such a study in detail and therefore there are bound to be some shortcomings in such a book. Perhaps too great a simplification is applied to the economic treatment of isotopes in medicine and agriculture where, for example, entomological considerations such as the sterile male technique are treated in a few lines without emphasizing the enormous economic advantages of this technique. On the other hand, food preservation or extension of the shelf-life of food has been treated in far more detail. The main emphasis, however, is on the industrial uses of isotopes and here some summaries and the main figures have been taken from the *I.A.E.A. International Survey on the Use of Isotopes in Industry*.

While the subject matter is surely of great interest to agriculturalists as well as to industrialists, the book is not written for them, or for the scientists or technicians. For the scientist it is perhaps too technical and for the technician it is not technical enough. It also has a bias to Belgian conditions.

I think that an industrialist, by quickly glancing through this book, might get quite a lot of first-hand information which might be useful to him although by no means comprehensive. A complete survey would be an extremely difficult, if not impossible, task.

Generally, it can be said that this book does not contribute much more, or in better form, than some of the publications referred to in its bibliography, but does contain some detailed information giving an idea of the field.

HENRY SELIGMAN

## Introduction to Atomic and Nuclear Physics

By Rogers D. Rusk. Pp. xiv+470+12 plates. (London: Iliffe Books, Ltd.; New York: Appleton-Century-Crofts, 1965.) 63s. net.

THIS book sets out to describe a large area of what is frequently called modern physics, aiming at providing an introduction for undergraduates. It treats a broad range of topics: quantum mechanics, relativity, atomic and molecular spectroscopy, nuclei, and glances at solid state physics and elementary particles. I think it is a failure, because the author is too frequently inaccurate, or expresses himself in a misleading way; in many cases these two possibilities are difficult to distinguish. As a reasonably typical example I quote from p. 323: "the suggestion by Heisenberg that the forces binding a proton in the nucleus to a neutron in the nucleus might arise from exchange of charge such that the proton momentarily becomes a neutron and the neutron momentarily becomes a proton and the two may scarcely be said to lead independent lives". Knowing something about this subject one can see some relation to the truth in these remarks but one cannot agree that they are correct; it is difficult to decide how much is actually wrong and how

much is misleading presentation. Whichever it is, an undergraduate would surely be confused. There is a high density of such confusing statements, in places at least one to each page, so that it seems impossible to recommend the book. I also remark on another fault, which also occurs in other books. Each chapter is followed by a short list of books for "Recommended Reading". These range from popular accounts to advanced textbooks, many covering a much wider area than the particular chapter. The chief result of such general recommendations, without any guidance about what can be recommended in each book, must surely be to produce severe indigestion. I think this practice should be deplored.

## Introduction to the Theory of Flow Mechanics

By Albert Betz. Translated by D. G. Randall. Pp. xvi+281. (London and New York: Pergamon Press, 1966.) 75s. net.

THIS book is an edited translation of the German work of Betz, first published in 1959. The difficulty with textbooks on turbo-machine theory (and there are not many) is that they are either too elementary or they present a collection of mathematical solutions of various problems in the field. Lack of space usually prohibits a thorough description of these solutions so that much of the material is available only in the original papers. This book suffers slightly from this fault—although it can be read with immediate profit. A good collection of references is included, many of them to original work of many years standing and to much of the German work.

The contents are roughly as follows: Some twenty pages are devoted to general principles, a fairly good knowledge of fluid mechanics being assumed. The next fifty pages briefly discuss flow in ducts, including topics such as diffusers and boundary layers in curved ducts. This is followed by some seventy pages on cascade theory in which approximate treatments of ideal fluid problems are interleaved with discussions of the effects of losses, compressibility and end effects. The remainder of the book, apart from the appendixes, contains a discussion of almost every type of flow machine (including very short descriptions of thermodynamic machines, such as ram-jets and pulse jets); the treatments are in many cases rather too brief. The appendixes refer mainly to the sections on cascade theory and include Betz's vortex influence charts and his cascade velocity and state diagrams. Perhaps the best part of the book is the section on cascade theory, although it is a pity that the translator could not have included an appendix on at least one of the theories outlined by Betz (in particular, the work of Isay). The translator is to be congratulated on achieving a most readable text.

J. W. RAILLY

## Problems of Atmospheric Circulation

Edited by R. V. Garcia and T. F. Malone. (A Session of the Sixth International Space Science Symposium, Mar del Plata, Argentina, May 11–19, 1965.) Pp. vi+186. (Washington, D.C.: Spartan Books; London: Macmillan and Co., Ltd., 1966.) 58s. net.

At a price which most research workers can afford for their private shelves, this book provides in one volume several review articles of the highest quality as well as much other material of great interest to all concerned with the broad problems of atmospheric physics.

There is a discussion on radiation and dynamics in the upper atmosphere from the vigorous laboratory at Leningrad under Professor K. Ya. Kondratiev. Professor R. E. Newell (Massachusetts Institute of Technology) contributes a brilliant survey of the energy and momentum budget of the atmosphere above the tropopause. W. L. Webb combines and discusses the results of the

American Meteorological Rocket Network up to January 1, 1965. There are details of the *EOLLE* drifting balloon experiment (P. Morel) and of the even more elaborate *GHOST* scheme (V. E. Lally). Professor K. P. Feoktistov and others give a fascinating account of various observations in atmospheric optics made by the Soviet astronauts aboard the *Voskhod*.

These and five other papers (I overlook two useless abstracts) rather more than fulfil the editors' claim to "offer an up-to-date account of the progress made in the use of rockets and satellites for meteorological research and of the promises for the near future".

The book is very well produced.

### Bio-organic Mechanisms

Vol. 2. By C. Thomas Bruice and Stephen J. Benkovic. (Frontiers in Chemistry Series.) Pp. viii+419. (New York and Amsterdam: W. A. Benjamin, Inc., 1966.) \$25.

THIS book is the second volume in Drs. Bruice and Benkovic's survey of bio-organic mechanisms, which they define as "those mechanistic studies likely to be of importance in the understanding of enzymic reactions or chemical transformation of biochemically important compounds such as the co-factors". This book is intended as a reference work for research workers and advanced graduate students and contains chapters on phosphate esters, phosphoro- and phosphonohalides, polyphosphates, thiamine pyrophosphate and pyridoxal-5-phosphate, nicotinamide, nucleotides, folic acid and biotin. It achieves its objective as a reference work on biorganic mechanisms from the standpoint of a physical organic chemist, and for this reason alone would make a valuable addition to an enzymologist's bookshelf. There is, however, a marked bias towards the study of model systems as opposed to studies on compounds of known biological significance and enzyme reaction mechanisms. For example, three chapters on phosphate derivatives without an adequate discussion of enzyme phosphate transfer mechanisms, the mode of action of phosphorohalides and the properties of nucleotides and polynucleotides cannot be described as "reasonably complete coverage". Nevertheless, the objectives of the book are fully realized in the succeeding chapters on enzyme co-factors. It is unfortunate that a chapter on flavins could not be included in this volume.

### Genetics of the Dog

The Basis of Successful Breeding. By Marca Burns and Margaret N. Fraser. Pp. viii+230+18 plates. (Edinburgh and London: Oliver and Boyd, Ltd., 1966.) 45s.

THE first edition of this book, by Dr. Marca Burns, a livestock breeding research worker and a breeder of cocker spaniels, appeared in 1952. The present edition, to which Miss Margaret Fraser, of the Commonwealth Bureau of Animal Breeding and Genetics, has contributed chapters on behaviour, is much enlarged, and the whole brought up to date in the light of much recent work on dog genetics. Genetic abnormalities in dogs, some of them distressing to the dog and unattractive to its owner, are common: some would say far too common, although the authors point out that they occur in mongrels perhaps as frequently as in show breeds. There is, however, little doubt that favouring certain extreme characters on the show bench can bring suffering to the dog and little credit to breeder or judge.

This balanced and well documented account of the genetics of the dog is written in language that any intelligent breeder can understand. It ought to lead to more sense and humanity in pedigree breeding than have been seen in certain breeds—bulldogs, dachshunds and German shepherds, to mention only three. There are eighteen plates (one in colour), 559 references, an index of breeds and a subject index. The book is well produced.

W. LANE-PETTER

## OBITUARIES

### Professor H. H. Swinnerton

EMERITUS PROFESSOR HENRY HURD SWINNERTON died on November 6, aged 91. He was a palaeontologist of world-wide repute, an outstanding teacher of the natural sciences and a man regarded with deep affection by many students and colleagues. Swinnerton belonged to a generation of scientists with many interests which it is difficult to match today. He took his degrees in London as a zoologist, and moved to the department of natural sciences at Nottingham to teach zoology, geology and botany, and developed the department of geography there; but he made his main scientific impact as a geologist, with archaeology and the study of modern land forms as sidelines.

He was awarded his D.Sc. at the Imperial College of Science and Technology, for investigation of the skeletons of the primitive lizard *Sphenodon* and modern fishes. There, influenced by Professor A. Morley Davies, he developed the interest in palaeontology which became his main scientific concern. In all his writings, and particularly in his classic textbook *Outlines of Palaeontology*, he stressed the dynamic aspects of evolution and classification, and in his presidential addresses to the Geological Society and to the British Association he dealt particularly with the mechanics of evolution. His other researches included work on the Triassic rocks of the Midlands and their fish faunas, the stratigraphy and fauna of the Cretaceous rocks of Lincolnshire, the glacial and post-glacial deposits of the East Midlands and the Lincolnshire coast and the physiographical development of eastern England. He also wrote a series of popular books on geology.

Apart from science he had a particular interest in young people and their intellectual problems—problems which had worried him while he resolved the conflict between religion and science—and he gave a great deal of his time to this in the Church and in the schools with which he was connected. In retirement Swinnerton continued his work on the Jurassic oyster *Gryphea*, a highly variable genus of which specimens were available at many horizons in numbers sufficient for statistical analysis; his final paper was published a year before his death.

P. E. KENT

### Michael Stewart Pease

MICHAEL PEASE died on July 27, aged 76. He had retired as director of the Poultry Research Station in 1957.

Pease took his natural sciences tripos and diploma in agriculture at Trinity College, Cambridge, in 1909–13. He went to Germany to do postgraduate work in genetics, but at the beginning of the First World War he was interned in Ruhleben camp. He returned to England in 1919, and joined Professor R. C. Punnett at the Small Animal Breeding Station, where they worked on the development of autosexing breeds of poultry—animals which show differential sex characters when they hatch.

In 1934 he went to the Animal Nutrition Institute, and from 1940 he was also in charge of the Small Animal Breeding Station. In 1951 he took up his last post at the Poultry Genetics Station and became a senior principal scientific officer. Until his retirement Pease worked mainly on the effects of inbreeding and subsequent crossing on poultry. Some of the lines of chickens which he developed are still used by immunologists, as the only highly inbred chickens available. Pease never held a university post, but he was a regular lecturer in animal genetics at the School of Agriculture in Cambridge.

Pease, who came of a Quaker family, was socially and politically very active. He was a parish councillor; a member of his rural district council for thirty-eight years, and of Cambridgeshire County Council for eight years. He received an O.B.E. for political and public service.

# High Energy Neutrons from the Sun

by

R. R. DANIEL  
GEORGE JOSEPH  
P. J. LAVAKARE  
R. SUNDERRAJAN

Tata Institute of Fundamental Research,  
Bombay

A balloon flight made from India on April 15, 1966, has provided new evidence that energetic neutrons can be produced directly in solar flares

THE emission of energetic neutrons from the Sun and their detection near the Earth could reveal the presence of fast charged particles in the coronal regions of the Sun. It would also help to provide information about conditions on the Sun at times of intense solar activity which would be free from the bias associated with the detection of fast charged solar particles near the Earth arising from the existence or otherwise of favourable conditions near the Sun and in interplanetary space. If the neutron production spectrum at the Sun is of the type deduced by Lingenfelter *et al.*<sup>1</sup>, then, because of the neutron half-life of about 12 min, the differential energy spectrum of the neutrons when they reach the Earth's orbit will have a maximum roughly in the region of 50–100 MeV if the proton spectrum responsible for the production of neutrons is assumed to be similar to that in solar proton events. The neutrons arriving in the vicinity of the Earth would reach the top of the atmosphere with equal intensity at all latitudes, thus implying that experiments made from equatorial latitudes will have an advantage in that the general background of neutrons produced by charged particles of galactic and solar origin will be a minimum. The first possible evidence for the production of solar neutrons was reported from this laboratory<sup>2</sup> from an experiment made with freshly coated nuclear emulsions flown in a balloon flight made on March 23, 1962, from Hyderabad (17°6' N., 78°5' E.). The purpose of the present report is to present the first positive evidence for a solar

neutron event using a scintillator-spark chamber detector assembly flown on April 15, 1966, also from Hyderabad.

The detector system shown in Fig. 1, consisting of the producer, the scintillators  $S_1$  and  $S_2$  and the spark chamber, was flanked on five sides by five plastic scintillators 1 cm thick each directly viewed by a 2 in. photomultiplier. The sixth side was left open for photographing the spark chamber. The discrimination levels for the pulses from  $S_1$  and  $S_2$  which trigger the spark chamber were separately set at a value corresponding to  $2.5 \times I_0$  where  $I_0$  is the ionization of a relativistic singly charged particle; this setting corresponds to an energy release of  $\geq 2$  MeV in each scintillator. The spark chamber was triggered, and an event recorded, when there was a coincidence pulse in  $S_1$  and  $S_2$  with no pulse in any of the anticoincidence scintillators; the event was recorded by photographing the spark chamber, together with a timer watch, by a stereoscopic camera. The recorded events were classified under the following six types: *Blank* is an event in which none of the spark gaps has fired,  $G_1$  represents an event in which only the top gap has fired,  $G_{1-2}$  is an event in which the two top gaps have fired and similarly  $G_{1-3}$ ,  $G_{1-4}$  and  $G_{1-5}$  are events in which the top three, four and five gaps respectively have fired.

The different kinds of events to which the present instrument could respond are the following: (i) Nuclear disintegrations produced within the anticoincidence shell by neutrons of energy  $\geq 50$  MeV. (ii) Favourable neutron-

Fig. 1. The high energy neutron detector.  $S_1$  is viewed by two photomultipliers through a light guide at right angles to that of  $S_2$ . The guard scintillators constitute the anticoincidence shield on five sides.

4007

R 347

proton elastic collisions occurring in the paraffin producer or the scintillators  $S_1$  and  $S_2$ ; for energies  $> 50$  MeV, events due to this process will be much less than 10 per cent of those due to (i); and for energies  $< 50$  MeV, it would be the most important process giving rise to events predominantly of types *Blank* and  $G_1$ . (iii)  $\gamma$ -Rays materializing within the anticoincidence shell; the efficiency of the detector for such events is very low because of the triggering system which demands an energy release  $\geq 2$  MeV in each of the two scintillators  $S_1$  and  $S_2$ . (iv) Slow secondary protons having the right geometry and energy, leaking into the detector through the camera window. Because of the geometry of the detector system such events also would contribute predominantly to *Blank* and  $G_1$  events only. (v) Fast protons entering through the camera window can produce nuclear disintegrations in any constituent part of the detector within the anticoincidence shell and, if the resulting secondary particles satisfy the triggering conditions, an event can be recorded. A simple estimate of this contribution from known fluxes of fast protons at the flight altitude, and the characteristics of interactions they produce, clearly shows that this kind of event will be  $< 10$  per cent of the events due to atmospheric neutrons at 10 mbar. It is clear from the foregoing observations that events of the type  $G_{1-2}$ ,  $G_{1-3}$ ,  $G_{1-4}$  and  $G_{1-5}$  arise mainly from nuclear disintegrations produced by high energy neutrons (process i).

The detector assembly was launched in a balloon flight made from Hyderabad, India, at 0717 IST on April 15, 1966. The balloon reached a ceiling altitude of 11 mbar at 0930 h and floated there at constant altitude (within about 1 mbar) till the instrument was cut down at 1345 h. The detector system was switched on when the balloon reached an altitude of 210 mbar. Owing to the high counting rate at the ceiling altitude, we could get records only up to 1100 h when the film was exhausted. The stereophotographs obtained during the flight were scanned and the counting rates determined for the different kinds of events for 10 min intervals. From an analysis of the spark

chamber photographs it was found that the efficiency of the top four gaps remained constant within statistical errors and had mean values of  $77 \pm 4$  per cent,  $83 \pm 4$  per cent,  $62 \pm 7$  per cent and  $80 \pm 10$  per cent for gaps  $G_1$ ,  $G_2$ ,  $G_3$  and  $G_4$  respectively.

A careful examination of the different counting rates summarized in Fig. 2 reveals three striking features which provide positive evidence for the emission of solar neutrons:

(i) There is a broad maximum in the total counting rate at  $\sim 100$  mbar (corresponding to the Pfotzer maximum) followed by a decrease which continues up to about 25 mbar where the counting rate is  $34.6 \pm 1.8$ ; it then starts increasing rapidly (beginning at about 0900 h) as though there was a sudden increase in the influx of particles responsible for the events.

(ii) The total counting rate has a value of  $49.6 \pm 2.2$  when the balloon reached the ceiling altitude and it continued to increase up to a maximum value of  $77.0 \pm 2.8$  during the time the balloon was at constant ceiling altitude; the general level of counting rate at the ceiling altitude is higher than that expected from secondary atmospheric particles by a factor of about three.

(iii) The variations in the counting rates at the constant ceiling altitude are far too large to be accounted for by statistical fluctuations.

That the detector system worked normally in the altitude region  $> 25$  mbar is seen from the fact that the absorption mean free path obtained from the present investigation between 1,000 mbar (ground observations) and 200 mbar is  $162 \pm 7$  g/cm<sup>2</sup>; this may be compared with the value of 150 g/cm<sup>2</sup> obtained by Hess *et al.*<sup>3</sup> for neutrons of energy  $> 50$  MeV.

If the particles activating the detector were all of secondary origin in the atmosphere, the counting rate would have continued to decrease between 25 and 11 mbar, and would then have remained constant at the ceiling altitude. The expected counting rate at the ceiling altitude obtained by extrapolating the straight line fitted for the

Fig. 2. Plot of the various counting rates as a function of pressure up to the point at which the balloon has just reached the ceiling altitude, and thereafter as a function of time. The solar radio emission at 100 Mc/s is also shown in the figure.

total counting rates recorded at the four levels of 80, 58, 39 and 28 mbar is only 23 per min. We have also been able to calculate the expected total counting rate at the ceiling altitude by making use of the flux of atmospheric neutrons of energy between 20 and 160 MeV measured by Apparao *et al.*<sup>2</sup> under almost identical flight conditions. The energy spectrum of the neutrons was then constructed using these data and the production spectrum for protons as given by Powell *et al.*<sup>4</sup>. We then calculated the counting rate by taking into account all possible contributions from nuclear disintegrations and elastically scattered protons due to neutrons of energy between 20 and 500 MeV, as well as from atmospheric protons leaking in through the camera window of the detector system. The calculated value thus obtained for the total counting rate is 16 per min with an accuracy better than 50 per cent. Considering this uncertainty in the calculations, this value seems to be consistent with the extrapolated value of 23 while the observed level of counting at the ceiling altitude is about three times this value.

It might be argued that the abnormally high counting rate and the large fluctuations observed at the ceiling altitude may be due to some erratic behaviour of the instrument which set in after about 0900 h. Such an erratic behaviour may arise from either (a) an erratic variation in the efficiency of the anticoincidence shield or (b) a similar behaviour of the triggering system unaccompanied by any charged particle traversing  $S_1$  and  $S_2$ . We have carefully considered these two possibilities and find that, if such erratic behaviour existed, the variations in counting rates should be restricted only to *Blank* and  $G_1$  types of events in (a) and to *Blank* events only in

(b). It is clear from Fig. 2, however, that events  $\sum_{n=2}^5 G_{1-n}$

do show an unambiguous correlation with the total counting rate. From these arguments we conclude that the large variations in the counting rates for different types of events observed beyond 25 mbar pressure level in Fig. 2 are due to real variations in the influx of neutrons responsible for the events.

The observed variation in the intensity of energetic neutrons can either be due to very large variations in the flux of charged primary cosmic rays (of solar or galactic origin) or to the arrival of neutrons which could only be of solar origin. In the same balloon flight as the present one, the Physical Research Laboratory, Ahmedabad, had a simple Geiger counter detector system, and this did not show any variation in the counting rate beyond statistical

fluctuations during the entire time when it was at the ceiling altitude. We therefore conclude that the large variations of counting rates we observed, when the equipment ascended beyond 25 mbar and was at ceiling altitude, were due to solar neutrons.

On April 15, when the present experiment was conducted, the Sun was under optical and radio observations at the Astrophysical Observatory, Kodaikanal. Judged from the brightening in the optical region (in H $\alpha$ ) and the enhancement of radio emission (at 100 Mc/s) the solar activity could be classified as a sub-flare. It seems very likely that this solar event and our observations on solar neutrons have a close relation.

The task of estimating the flux of solar neutrons in the present experiment was made very difficult because of the difficulty of separating the contribution of events due to neutron-proton elastic collisions at lower energies. If, however, all events other than *Blanks* and  $G_1$  are attributed to stars produced by energetic neutrons—that this is reasonable has been shown early in this article—one can obtain a rough estimate of the average flux of solar neutrons for the 1.5 h of observations as  $\sim 1,000 \text{ m}^{-2} \text{ sec}^{-1}$  in the energy interval of 50–500 MeV.

To summarize: (i) we have obtained, for the first time, positive evidence for the emission of high energy neutrons from the Sun; (ii) the observations indicate that the neutron emission set in at about 0900 h IST on April 15, 1966, and continued for at least about 90 min and during this time the neutron intensity seems to pulsate with periods  $\leq 10$  min; and (iii) there seems to be a plausible association between this neutron event and a sub-solar flare.

We are grateful to the Balloon Flight Group of this Institute for the successful flight operations, to Mr. George Abraham for the excellent technical help, to Dr. G. S. Gokhale for help and suggestions in different stages of this experiment and to Professor M. G. K. Menon for useful suggestions regarding the preparation of this paper. Our thanks are also due to Dr. Vainu Bappu, Director of the Kodaikanal Observatory, and Dr. N. W. Nerurkar, Physical Research Laboratory, Ahmedabad, for permitting us to quote their data here.

## Supersonic Liquid Jets

by

J. D. O'KEEFE  
W. W. WRINKLE  
C. N. SCULLY

Space and Information Systems Division,  
North American Aviation Inc.,  
Downey, California

Liquid jets have been produced by ballistic extrusion with velocities of 4.58 km/sec

This article describes the development of methods for the production of very high velocity liquid jets. These can be used to study problems associated with the impact of very high velocity liquid droplets and jets with solids and liquids, including luminous radiation from droplet collisions and the use of high velocity liquid streams for the acceleration of spheres and irregularly shaped objects using the liquid as sabot. Previous workers<sup>1,2</sup> have used an impact acceleration technique for obtaining velocities up to 1.1 km/sec (3,600 ft./sec). By using liquid columns, usually water, accelerated in the smooth

bore of a smokeless powder gun and extruding the liquid column through a converging tapered section fixed to the end of the gun barrel, we have achieved water jet velocities of up to 4.58 km/sec (15,000 ft./sec).

A smooth-bore smokeless powder gun of bore diameter 1.145 cm was used to fire water columns vertically through convergent conical tapered sections into an evacuated (0.2 torr) 'Lucite' chamber. Before firing, each water column was supported in the gun barrel by a tight fitting Lexan piston. A 'Mylar' diaphragm 1 mil thick between the evacuated chamber and the water column prevented

Fig. 1. Water jet effluxing from nozzle for various conditions. *a*, Input velocity 1.77 km/sec (5,800 ft./sec), 12/1 area ratio, 8 cm length, efflux velocity 4.58 km/sec (15,000 ft./sec). Typical high velocity jet. *b*, Input velocity 0.66 km/sec (2,180 ft./sec), 12/1 area ratio, 8 cm water, efflux velocity 1.91 km/sec (6,250 ft./sec). Typical low velocity jet. *c*, Radially expanding pulse resulting from the formation of a shock front. *d*, Jet expanding into air at one atmosphere pressure with input velocity of 1.22 km/sec (4,000 ft./sec), 12/1 area ratio, 8 cm water column and efflux velocity of 2.88 km/sec (9,400 ft./sec).

evaporation, and water columns 4, 6, 8, 12 and 16 cm long were fired. The gun was calibrated for the various projectile weights and fired the piston water column at velocities from 0.714 to 1.90 km/sec into a steel conical tapered section screwed directly to the end of the gun barrel. The tapers all had half-angles of  $1.5^\circ$  and large diameters matching the gun bore, but were of different lengths and, therefore, of different area ratios (ratio of area of gun bore cross section to area of exit end of taper). The velocities of the leading edges of the water jets were derived from time and position data obtained from 'Dynafax' camera records taken at 25,000 frames per second.

The motion of the water column in the converging taper section can be adequately described by the one dimensional, unsteady equations of compressible fluid flow with a slowly varying cross-sectional area ratio in Eulerian co-ordinates<sup>3</sup>. These are

$$\begin{aligned}\frac{\partial \rho}{\partial t} + \rho \frac{\partial u}{\partial x} + u \frac{\partial \rho}{\partial x} + \frac{\rho u}{A} \frac{\partial A}{\partial x} &= 0 \\ \frac{\partial u}{\partial t} + u \frac{\partial u}{\partial x} + \frac{1}{\rho} \frac{\partial p}{\partial x} &= 0 \\ \frac{dp}{dt} - c^2 \frac{d\rho}{dt} &= 0\end{aligned}$$

From this system may be obtained the physical characteristic equations

$$\frac{dx}{dt} = u \pm c$$

and the corresponding state characteristic equations

$$du = \mp \frac{1}{\rho c} \left( \frac{\partial p}{\partial c} \right)_s dc \mp \frac{1}{A} \frac{dA}{dx} dx$$

where  $\rho$ ,  $p$ ,  $u$ ,  $c$  are the density, pressure, velocity and sonic velocity of the fluid and  $A$  is the cross-sectional area. The left bounding characteristic is given by the equation of the piston path and the pressure condition behind it by

$$\begin{aligned}\frac{dx}{dt} &= u \\ p &= p_b - \frac{m_p}{A} \frac{du}{dt}\end{aligned}$$

where  $m_p$  is the mass of the piston and  $p_b$  is the gas pressure behind the piston. The right bounding characteristic is given by the equation of the free surface and its pressure condition

$$\begin{aligned}\frac{dx}{dt} &= u \\ p_f &= 0\end{aligned}$$

where  $p_f$  is the free surface pressure.

The equation of state of water was given by Tait<sup>4</sup>

$$p = 2.94 \left\{ \left( \frac{\rho}{\rho_0} \right)^{7.47} - 1 \right\}$$

The boundary conditions corresponding to the experimental configuration were  $p_b = 0.216$  kbar; a constant piston sectional density of 1 g/cm<sup>2</sup> at  $t=0$ , a uniform pressure, density and velocity in the columns and one atmosphere of pressure on the free surface of the liquid, and the free surface positioned at the beginning of the converging section.

The above equations with appropriate boundary conditions were numerically integrated on an IBM 7094 computer using an iterative technique similar to that given in Shapiro<sup>5</sup>.

Fig. 2. Characteristic mesh for following conditions, input velocity 1.22 km/sec (4,000 ft./sec), 12/1 area ratio, piston mass = 0, converging section terminates at 3.12.

Fig. 3. Stereoscopic pair of pressure-time history for conditions in Fig. 2.

The dynamics of the process are illustrated in the characteristic plots (Figs. 2 and 3). The pressure pulses produced as the water column enters the converging section propagate into the liquid at velocities  $u \pm c$  where  $u$  is the local fluid velocity and  $c$  is the local sonic velocity. The curvature of the characteristics is a function of the strength of the pressure pulses. If the right or left running characteristics intersect, a right or left running shock will be formed at that time. In Fig. 2 for the conditions given, there is no shock formed because the pulses have partially transmitted their pressure and momentum to the boundaries of the column. The case where a water column enters the converging section supersonically is similar, but when a rear running shock is formed it will be stationary near the entrance of the converging section.

The calculated jet velocities did not include the effect of the vaporization, with the result that the velocities were under-estimated. To confirm the analysis, a jet was extruded into an ambient atmosphere at 1 bar (Fig. 1d). The calculated and the experimental values agreed within 3 per cent.

Figs. 4a and 4b illustrate the effect of input velocity and area ratio on jet velocity. In the velocity range considered, the jet velocity does not reflect processes typical of an incompressible fluid.

The effect of initial column length on jet velocity is shown in Fig. 5a. The leading edge velocity increases linearly up to some critical length, depending on the piston

Fig. 4a. Jet velocity versus input velocity for constant 12/1 area ratio, 8 cm water column.

Fig. 4b. Jet velocity versus area ratio for constant input velocity of 1.22 km/sec (4,000 ft./sec), 8 cm water column.

Fig. 5a. Jet velocity versus column length divided by taper length for constant input velocity 1.22 km/sec (4,000 ft./sec), 8 cm water column.

Fig. 5b. Calculated peak taper pressure versus column length divided by taper length for constant input velocity 1.22 km/sec (4,000 ft./sec) and 12/1 area ratio.

mass and the taper angle. The analysis is carried out for zero piston mass, which for the conditions in Fig. 2 gives the maximum initial column length that can be used before a shock would be formed.

The pressure-time history of the column is shown in the stereoscopic pair<sup>6</sup> in Fig. 3. As can be seen, the pressure gradients increase rapidly in time, causing the leading edge of the column to accelerate supersonically. In Fig. 5b the calculated peak pressures for various column lengths are plotted, and in the cases where a shock is formed the pressure at the beginning of formation is given. When the entrance velocity was supersonic, pressures of 11 kbar were produced, and were great enough to cause a radial expansion of the hardened steel taper sections.

Two piston densities were used, 1 g/cm<sup>3</sup> and 8.5 g/cm<sup>3</sup>, for the conditions given in Fig. 2 and for the 12 to 1 taper ratio. The denser piston increased the jet velocity from 3.51 km/sec (11,500 ft./sec) to 4.13 km/sec (13,500 ft./sec).

The yield strength of the steel taper sections appears to be the factor which limits the maximum jet velocities. Small changes in efflux velocity cause large changes in taper pressure.

# Radioactive Ruthenium and Manganese Isotopes in the Atmosphere

by

M. N. RAO

Miss K. K. MENON\*

Department of Chemistry,  
University of Arkansas,  
Fayetteville, Arkansas

The movement of air masses between the stratosphere and the troposphere can be traced by studying the concentration and ratios of radioactive ruthenium and manganese injected into the atmosphere by nuclear bursts on the ground and in the air

RADIOACTIVE debris injected into the atmosphere by ground and air nuclear bursts is well suited for tracing the movements of air masses between the stratosphere and the troposphere. This air transport is studied by determining the concentrations of the products of fission and neutron activation in the air samples collected by filtering large volumes of air at various altitudes and latitudes in the atmosphere. Filter samples, collected between July 1962 and October 1963 in the northern hemisphere up to an altitude of 68,000 ft. in connexion with the Star Dust Program, were received in the autumn of 1963 by the University of Arkansas. The results of analyses of these samples for antimony-125 and antimony-124 have been published by Kauranen<sup>1</sup>. In this report we present the results of analyses for ruthenium-106 (rhodium-106) and manganese-54.

The filter samples were decomposed and brought into solution according to the methods described by Friend *et al.*<sup>2</sup>. From a large portion of this solution, the sulphides of antimony, tin, ruthenium and manganese were precipitated and antimony was separated from them as described by Kauranen<sup>1</sup>. The remaining solution was processed for ruthenium as described by Rao and Shahani<sup>3</sup> and manganese was subsequently precipitated as dioxide. The chemical yields were usually about 60 per cent. The introduction of any oxidizing agents was carefully avoided while the filters were being decomposed. The ruthenium and manganese samples were counted with a 3 in.  $\times$  3 in. sodium iodide (thallium doped) crystal in a 512 channel pulse-height analyser and the  $\gamma$ -ray spectra showed that both the ruthenium and manganese samples were pure. In order to calculate the respective concentrations, 0.513 MeV  $\gamma$ -ray peak for ruthenium-106 (rhodium-106) and 0.84 MeV  $\gamma$ -ray peak for manganese-54 were used.

The concentrations of ruthenium-106 (rhodium-106) and manganese-54 and the ratios of ruthenium-106 : manganese-54 in the northern hemisphere at different seasons in 1962 and 1963, as a function of latitude and altitude, are summarized in Fig. 1. The data are calculated in disintegrations per minute (d.p.m.) per standard cubic foot (scf) at the time of collection and they are corrected for decay to January 1, 1963. The overall error in these values is assumed to be about 20 per cent. The air volumes and the tropopause heights were provided for us by Dr. Feely of Isotope, Inc., Westwood, New Jersey.

Despite several tests carried out by the United States and the Soviet Union in 1961 and early 1962, the concentrations of ruthenium-106 shown in Fig. 1A are quite low (1–3 d.p.m./scf) in the northern stratosphere by July and September 1962. But the corresponding concentrations of manganese-54, also shown in Fig. 1A, are rather high (12 d.p.m./scf) in July and September 1962.

In the autumn of 1962, a series of large-scale nuclear tests were carried out by the U.S.S.R. at Novaya Zemlya (76° N.) and some high altitude tests by the United States at Johnston Island (17° N.). As a result of these tests, there was a considerable increase in the concentrations of ruthenium-106 throughout the northern stratosphere by January 1963. The concentrations of ruthenium-106 at polar and mid-latitudes between 60,000 and 70,000 ft. are about 2–3 times higher than the ruthenium-106 activity in tropical latitudes, which indicates that the contribution of fission-product debris into the lower stratosphere by Soviet tests was much higher than that of American tests. But the concentrations of manganese-54 did not show such an increase at this time at polar and tropical latitudes. According to Holland<sup>4</sup>, manganese-54 appears to have been produced largely in the 55–60 megaton Soviet arctic thermonuclear detonation in October 1961. All nuclear explosions involving fission-type bombs contribute, however, to the production of ruthenium-106.

A study of the concentrations of ruthenium-106 and manganese-54 and their ratios in Fig. 1A–D shows that a semi-horizontal mixing is taking place in the lower stratosphere. Fig. 1A shows that a ruthenium-106 activity of 1.5 d.p.m./scf was located at 65° N. and 62,000 ft. by September 1962, and Fig. 1B shows that this activity had increased enormously by January 1963 as a result of Soviet tests, giving rise to a maximum ruthenium-106 activity of 122 d.p.m./scf at the same latitude and altitude as already mentioned. A part of this huge ruthenium-106 activity, introduced into the polar stratosphere by Soviet tests in the autumn of 1962, appears to have migrated southward by January 1963 to 45° N. and 60,000 ft. where the air samples showed a ruthenium-106 activity of 103 d.p.m./scf, as shown in Fig. 1B. Furthermore, the ratios of ruthenium-106 : manganese-54 in January 1963 in these two regions seem to be the same, as indicated by the ratio-isoline of 18 in Fig. 1B. A similar trend is also observed in the case of manganese-54. As shown in Fig. 1A, by September 1962, a manganese-54 activity of 10 d.p.m./scf occurred at 63° N. and 63,000 ft. But by January 1963, as shown in Fig. 1B, this centre of manganese-54 activity had moved southward to 43° N. and 61,000 ft. These observations seem to indicate that in winter 1962 and early spring 1963, the ruthenium-106 and manganese-54 activities moved southwards from the North Pole to mid-latitudes at about 70,000 ft.

An evidence of northward and downward movement of the lower stratospheric air (at about 50,000 ft.) from tropics to mid-latitudes and probably into lower polar regions could be found in winter and spring from a study of Figs. 1A–D. The ruthenium-106/manganese-54 ratio-isolines of 5 and 9 in Fig. 1B show a tendency to slope northward and downward, and the concentration isolines in this figure also show the same trend. By April 1963,

\* Present address: Division of Physical Science, Maycrest College, Davenport, Iowa.

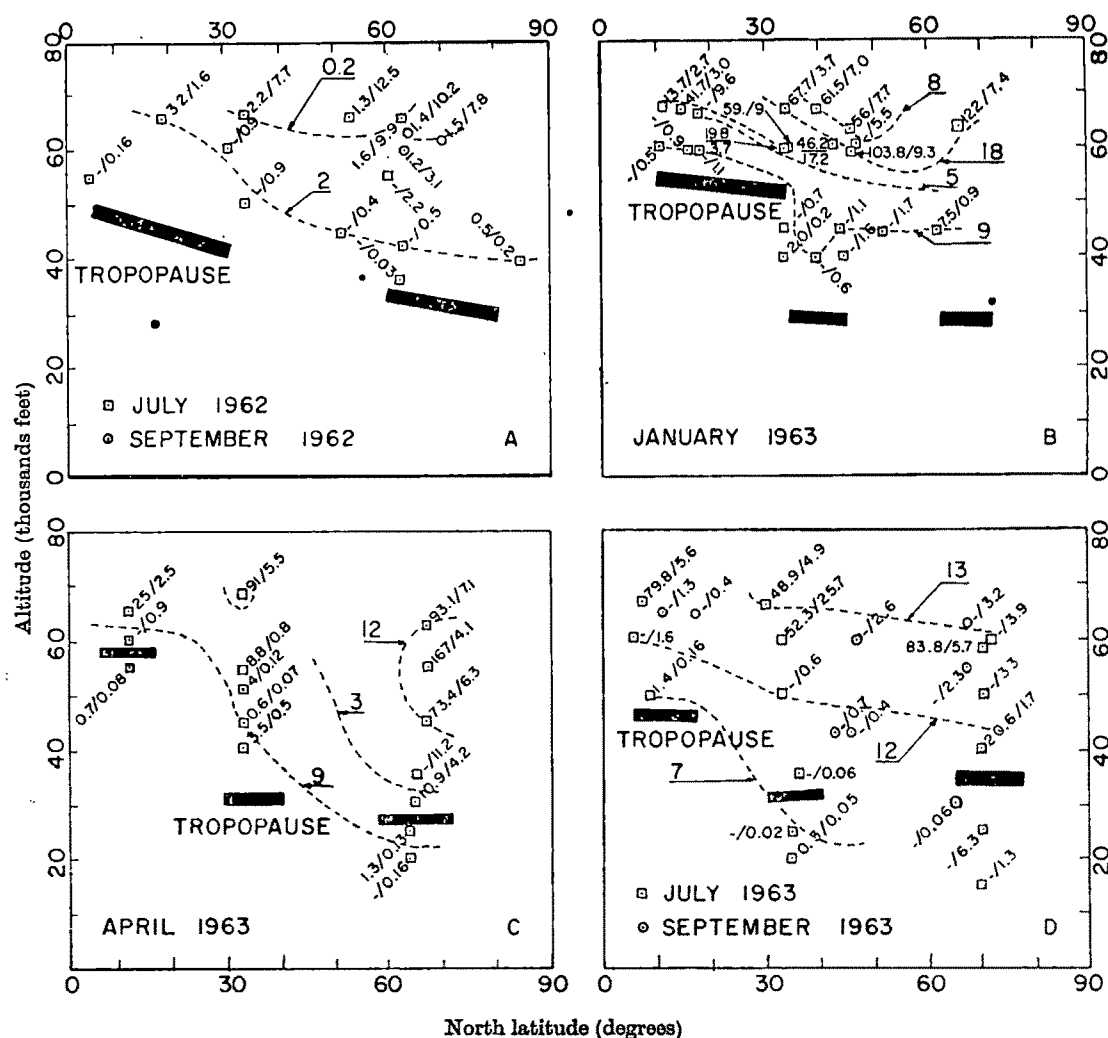

Fig. 1. Concentrations and ratios of ruthenium-106 and manganese-54 in the northern hemisphere during July 1962–September 1963. The values are given in d.p.m./sof. Near the squares in the figure values for ruthenium-106 and manganese-54 are given as, for example, 50/5.1, where the value of the numerator represents the concentration of ruthenium-106 in d.p.m./sof and the value of the denominator represents the manganese-54 concentration in d.p.m./sof. In cases where the values for a particular nuclide were not determined, they are indicated as —. The dashed lines represent the ratio-isolines of ruthenium-106 : manganese-54 and the corresponding values are indicated by the arrows.

however, as shown in Fig. 1C, the ruthenium-106/manganese-54 ratio-isoline of 9 shows a steep downward and northward slope from tropics to pole. Another example of northward and downward movement of lower stratospheric air could be found in the air mass at 45° N. and 60,000 ft., with a ratio of ruthenium-106 : manganese-54 of 3 (as shown in Fig. 1B) from winter 1963, which has moved to 65° N. and 45,000 ft. by spring 1963 (as shown in Fig. 1C). The concentrations of ruthenium-106 and manganese-54 in this air mass also show the same trend. This type of air transport seems to contribute much to the increased concentrations of these nuclides, detected in the lower polar stratosphere by spring 1963. In addition, the vertical mixing as a result of the formation of polar cyclonic vortex in winter in the lower stratosphere contributes significantly to the "Spring-Peak" resulting in the increased concentrations of the fission products in rainfall by spring time<sup>5</sup>.

Our data in Figs. 1A–D show that air can pass between the stratosphere and the troposphere in the vicinity of the jet stream and the tropopause discontinuity, as proposed by Staley<sup>6</sup> and Newell<sup>7</sup>. In Fig. 1C, the ruthenium-106/manganese-54 ratio-isoline of 9 in the lower stratosphere follows the path of the tropopause indicating higher con-

centrations above the tropopause surfaces and protrudes into the troposphere near the jet stream region in the mid-latitudes. In Fig. 1B the ruthenium-106/manganese-54 ratio-isolines of 9, and in Fig. 1D the ratio-isoline of 7, also show a similar tendency. Further attempts are in progress in this laboratory to study the movement of air masses in the stratosphere with the help of strontium-90 and cerium-144 distributions and comparing them with these results.

We thank Prof. P. K. Kuroda for his encouragement and many helpful discussions during the course of this work. This work is supported by a contract with the U.S. Atomic Energy Commission.

# Dielectric Absorption of Microwaves in Human Tissues \*

by

J. R. MALLARD†

D. G. LAWN‡

Department of Physics and Biophysics,  
St. Thomas's Hospital Medical School,  
London, S.E.1

Calculations show that differences in absorption of microwaves by the human body may be a means of localizing tumours and some body structures

MEASUREMENTS of the electron spin resonance from "surviving" animal tissues at 3 cm wavelength have shown a difference in the amount of resonance absorption at room temperature at  $g=2.004$ , between malignant and normal tissue<sup>1-4</sup>. The signal for normal rat liver is some twenty times greater than that for rat liver tumour, while at  $g=2.016$  a broad absorption signal from rat hepatoma and metastases has been observed which is absent in normal rat liver tissue<sup>4</sup>.

It is more difficult to obtain suitable samples of human tumours and normal tissues for comparison, but preliminary measurements indicate that a differential exists between some tumours and the corresponding normal tissue. Using a reliable spectrometer of high sensitivity and reproducibility, it is therefore possible to distinguish between normal and malignant tissue samples, but this would be a cumbersome and expensive way of discriminating between them when the examination of a section under the microscope would give the same information and more.

One wonders whether a machine using electron spin resonance could be constructed which could measure or display *in vivo* the differential between the normal tissue and the tumour embedded within it: is it possible that a machine which detects and measures the transmitted intensity of microwaves through the body could scan the region of interest to display and localize a tumour? The first question to answer in the design of such a machine is how much of a beam of microwaves incident on the body would emerge after transmission through the body, or after reflexion from the interface between tumour and normal tissue within the body.

First, the considerable dielectric absorption of the microwave beam by the body tissues must be calculated and it is here that some interesting observations can be made. Experimental information on the dielectric constant of human tissues is sparse. England and Sharples<sup>5</sup> and England<sup>6</sup> have at 3 cm reported values of the power absorption coefficient ranging from  $\alpha=2.65$  to 3.2 (average value 2.84) for six samples of breast carcinoma (scirrhous) and a value of  $\alpha=0.49$  (leg fat  $\alpha=0.44$ ) for breast fat. Thus there is a difference in dielectric constants for a particular tumour and what might be regarded as its surrounding tissue. The tumour value reported was also

slightly different from that of other soft tissue (for example, skeletal muscle  $\alpha=2.60$ ), but Buchanan (personal communication) has pointed out the great difficulty of such measurements and the uncertainties which are attached to smaller differences. It would appear that a more extensive series of dielectric measurements on tissue samples is needed to establish values more accurately from tissue to tissue and to investigate the reality of any differences between tumours and normal tissues. For the calculation of tissue absorption reported in this preliminary study, the values of England and Sharples<sup>5</sup> have been used throughout.

The calculations have been carried out for the model shown in Fig. 1. A slab of breast fat 10 cm thick has a tumour of 1 cm thickness embedded within it, the position of the tumour being defined by  $l_2$ . The waves propagated in the tissues are attenuated, reflected and changed in phase: diffraction will also occur, but this was not taken into account in this simple model.

Fig. 1. Diagram of the model used for the calculations. A breast tumour ( $\alpha=2.84$ ) of thickness 1 cm is embedded in breast fat ( $\alpha=0.44$ ) and is irradiated with 3 cm microwaves. The transmitted and reflected intensities ( $P_R$  and  $P_T$ ) are calculated both with and without the tumour (see Fig. 2).

If  $P(x)$  is the power at  $x$ , then  $P(x) = P(0) e^{-\alpha x}$  where  $\alpha$  is the linear power absorption coefficient.

Let  $a$  and  $b$  (see Fig. 1) be the wave amplitudes and let  $R$  and  $T$  be the reflexion and transmission coefficients, then at an interface (for example, face 1)

$$1 + R_1 = T_{0,1}$$

For the model in Fig. 1

$$\begin{bmatrix} a_1 \\ b_1 \end{bmatrix} = \frac{1}{T_{1,2} \cdot T_{2,3} \cdot T_{3,4}} \cdot [A] \begin{bmatrix} a_4 \\ 0 \end{bmatrix}$$

\* This material is part of that presented at the First International Conference of Medical Physics, Harrogate, 1965, and the Eleventh International Congress of Radiology, Rome, 1965.

† Present address: Department of Medical Physics, University of Aberdeen, Scotland.

‡ Present address: Institut für Biophysik, Freie Universität, West Berlin.

$$\text{where } [A] = \prod_{j=1}^3 B^j \text{ and } B^j = \begin{bmatrix} 0 & 1 \\ e^{-i\varphi_j} & R_{j+1} \end{bmatrix} \begin{bmatrix} 1 & R_{j+1} \\ R_{j+1} & 1 \end{bmatrix}$$

and the complex propagation factor  $\varphi_j = \left(k_j - \frac{i\alpha_j}{2}\right)l_j$  and

( $j=1, 3$  for fat;  $j=2$  for tumour)

with  $\lambda_j$  the wavelength,  $k_j = 2\pi/\lambda_j$ ,  $\alpha_j$  = absorption coefficient in the medium  $j$  and  $l_j$  = length of medium.

This matrix expresses the relation between the transmitted amplitude  $a_4$  and the amplitudes  $a_1$  and  $b_1$  which result from multiple reflexions, phase changes and absorption.

Defining  $T = a_4/a_1$

and  $R = b_1/a_1$ ,

$$\text{then } T = \frac{T_{1,2} \cdot T_{2,3} \cdot T_{3,4}}{A_{11}} \text{ and } R = \frac{A_{21}}{A_{11}}$$

Referring to Fig. 1,

$$P_T = P_{in} \cdot |T|^2 \cdot |T_{0,1}|^2 \cdot 1/(1 + RR_1)^2$$

and

$$P_R = P_{in}(R + R_1)^2/(1 + RR_1)^2$$

The transmission coefficients and  $R_1$  are found from the dielectric constants of the media, and it only remains to calculate  $A_{11}$  and  $A_{21}$  in order to determine  $R$  and  $T$ .

Fig. 2. The results of the calculations plotted against  $l_3$ , the position of the 1 cm thick tumour, for the model of Fig. 1.

$$Q_T = \frac{\text{Transmitted power with tumour}}{\text{Transmitted power without tumour (fat only)}}$$

$$Q_R = \frac{\text{Reflected power with tumour}}{\text{Reflected power without tumour (fat only)}}$$

The matrix elements give  $|A_{11}|^2$  and  $|A_{21}|^2$  as functions of  $\alpha_1$ ,  $\alpha_2$ ,  $l_3$ ,  $R_1$ ,  $k_2$  and  $k_3$  which are calculated for various values of  $l_3$  and also for the case when no tumour is present.

The following ratios are obtained.

$$Q_T = \frac{P_T \text{ with tumour}}{P_T \text{ fat only}}$$

and

$$Q_R = \frac{P_R \text{ with tumour}}{P_R \text{ fat only}}$$

which are plotted in Fig. 2. The values of  $Q_T$  and  $Q_R$  are related to the input power  $P_{in}$  by the ratio of  $P_T/P_{in}$  in the absence of tumour. For 10 cm of fat without tumour

$$P_T/P_{in} = 1.8 \times 10^{-3}$$

$$\text{and } P_R/P_{in} = 0.12$$

The values of  $Q_T$  in Fig. 2 show that the transmitted power through the tumour and fat is less than one-fifth of that through fat alone and that the transmitted power is greatest through the model when the tumour is centrally placed in the fat. The values of  $Q_R$  in Fig. 2 show that, as the tumour is moved from the back face to the incident face, the reflected power increases from 0.12 to greater than 0.5.

Fig. 3. The results of the calculations plotted in the same way as Fig. 2, when a layer of skin 1 mm thick ( $\alpha = 2.60$ ) is added to Faces 1 and 4 of the model shown in Fig. 1.

It would seem possible, therefore, that the presence of breast tumour tissue in this model could be demonstrated either by reflexion or transmission. Because of heating effects it is recommended that the continuous incident power at the surface of the body must not exceed 10 mW/cm<sup>2</sup>, over a frequency range from 30 Mc/s to 30 Gc/s, for a human being<sup>7</sup>. As a result the transmitted power levels would be of the order of 10<sup>-5</sup> W/cm<sup>2</sup> for the model considered here. It is possible that a more intense short pulse could be used in order to increase the power to be detected but only with great care.

For this model, the differential of intensity beneath the tumour to that of the surrounding regions is greater than would be achieved in *in vivo* diagnostic radiography. The model taken, however, has been a favourable one because of the considerable difference of dielectric constant reported by England and Sharples<sup>8</sup> for breast fat and breast tumour. The calculations have been performed also on the much less favourable case of the breast tumour

Fig. 4. *a*, Summary of calculated results for the model shown in Fig. 1, 10 cm thick. The central figure shows the results with a 1 mm thick skin layer added as shown, whilst the lowest figure has the breast fat replaced with muscle. There is a much greater difference in transmitted intensity with and without tumour when skin is added, and a much smaller difference when fat is replaced with muscle. *b*, Summary of the calculated results for a model of a 1 cm breast tumour embedded in 3 cm of breast fat (upper figure) and muscle (lower figure). In addition, the extra absorption caused by electron spin resonance (E.S.R.) processes is also shown. E.S.R. calculations assume tumour has  $\approx 10^{16}$  spins/g and normal tissue has  $\approx 10^{15}$  spins/g.

( $\alpha = 2.84$ ) embedded in muscle ( $\alpha = 2.60$ ). In this case, for a centrally placed tumour,

$$Q_T = 0.79 \text{ and } Q_R = 1$$

If this 20 per cent change in transmitted intensity does occur *in vivo*, then it should be possible to detect it.

Further calculations were carried out for the model of Fig. 1 with the addition on Faces 1 and 4 of a layer of skin 1 mm thick ( $\alpha = 2.60$ ). The matrix elements are more complex and lead to the result of Fig. 3. The transmission case is approximately symmetrical and the large effect with the tumour near the edges is caused by the importance of the phase angle when there is a small distance between two tissues of similar dielectric constant. The ratio of the transmitted power, with and without tumour, is even greater than before and the output power levels are measurable. In these circumstances  $P_T/P_{in} = 2.55 \times 10^{-4}$  and  $P_R/P_{in} = 0.74$ .

Very useful reductions in unwanted reflexions can be made by matching the impedances of materials at interfaces, that is, by blooming the surfaces. For example, the two skin-air interfaces can be matched by coating them with a material, the dielectric constant ( $K$ ) of which is related to those on either side by  $K = (K_{air} \cdot K_{skin})^{1/2}$ . Such a coating will approximately match impedance, not only for the incident waves which travel inwards but also for the emergent waves which travel outwards; it would also increase still further the ratio between tumour and non-tumour intensities.

Fig. 4(a) summarizes the results on the 10 cm thick model with and without skin, while Fig. 4(b) presents the results on a model which is only 3 cm thick. For the case of this smaller model, the extra absorption of microwaves due to electron spin resonance processes, with the model placed in a magnetic field of 3,400 G, has been calculated. It has been assumed in these calculations that the tumour has a concentration of approximately  $10^{16}$  spins/g, and normal tissue approximately  $10^{15}$  spins/g, which are the values determined for rat liver and rat liver tumour<sup>4</sup>. It is seen that the electron spin resonance absorption of microwaves is very small (about  $10^{-4}$ ) compared with the dielectric absorption. As a result, the detection of the difference in electron spin resonance absorption between tumour and normal tissue, by a machine based on the rationale discussed here, would seem to be a more formidable task than the detection of the difference arising from dielectric properties.

It seems likely that by measuring the transmission of microwaves through the body, it should be possible to demonstrate differences in dielectric absorption from point to point in the body and perhaps outline and localize—by photographic or scanning methods—tissues or body cavities, or abnormal regions of organs which have different dielectric constants. It seems possible that this might have some value for tumour detection and localization. Perhaps the technique of holography may prove to be an aid in this procedure. The reflected beam should enable interfaces (particularly mobile interfaces) to be detected in a similar manner to ultrasonic localization methods. It is realized that the practical difficulties are considerable.

We thank Mr. M. Kent, with whom this work has evolved, for his help and comments, and Dr. T. J. Buchanan for reading and checking the calculations. We also thank the Science Research Council for support.

# Killing of Staphylococci by Penicillins

by

H. J. ROGERS

National Institute for Medical Research,  
Mill Hill, London, N.W.7

What happens after the inhibition of cell wall synthesis by penicillins?  
Effects of antibiotics suggest that mucopeptidase plays an important  
part by destroying mucopeptide

THE penicillins inhibit the formation of mucopeptide in bacterial cell walls<sup>1,2</sup> and when staphylococci are tested under suitable conditions this can be shown to occur without lag and with minimal growth inhibitory concentrations of the antibiotics<sup>3,4</sup>. The particular step in the biosynthesis of the complex polymer which is inhibited is likely to be a very late one<sup>5,6</sup>. Inhibition of growth and mucopeptide synthesis<sup>7</sup> is reversible and is not followed by death of the bacteria unless they have grown for a sufficient time in the antibiotic (succeeding article). Death of the cells is thus not related by an obvious mechanism to the primary inhibition of the formation of cell walls, although fairly rapid permeability changes have been shown in *Escherichia coli*, *Erwinia* and *Staphylococcus aureus* as a result of growing the bacteria in media containing penicillin.

The present work is intended to define the steps that follow the inhibition of cell wall synthesis. Two considerations form the basis of this work. The first is derived from the observation that the penicillins in high concentrations do not directly inhibit protein formation<sup>3,4</sup>. It is, therefore, presumed that at low concentrations they have no effect on the formation of wall lytic enzymes (mucopeptidases) by the cell although, as described later, it eventually became necessary to suppose that at concentrations considerably higher than those that just inhibit growth they could specifically depress the formation of mucopeptidases. The second is that all bacteria produce autolytic enzymes, called here mucopeptidases, that can attack mucopeptide. A number have already been described<sup>8,9</sup> which attack the structure at a number of points. The possible roles of autolytic enzymes in the remodelling of the wall of bacteria have been discussed<sup>10,11</sup>. Some enzyme which hydrolyses mucopeptide probably would be essential for normal wall extension and division of a micro-organism.

It is known that the bactericidal effects of benzylpenicillin on streptococci and *E. coli* can be antagonized by the simultaneous presence of other antibiotics such as chloramphenicol<sup>12,13</sup>. Fig. 1 and Table 1 show that both lysis and death of staphylococci caused by the addition of methicillin to cultures growing in a dilute casein hydrolysate medium can be prevented by chloramphenicol, provided the latter is added not later than 15 min after the penicillin. This argues that, provided protein synthesis is switched off within a time that corresponded to about a fifth of a generation time (70 min) in the medium used, irreversible damage to the cell is not caused by the inhibition of mucopeptide synthesis. The correlation of the lytic effect on the cells with the antagonism of the bactericidal effects suggested that the continued formation of a mucopeptidase might be a factor leading to the death of staphylococci. The effects of excess chloramphenicol and the growth-inhibitory concentration of methicillin on the amounts of mucopeptide formed by staphylococci incubated in a casein hydrolysate growth medium are

Table 1. NUMBER OF LIVING BACTERIA IN CULTURES INCUBATED WITH METHICILLIN AND WITH CHLORAMPHENICOL ADDED AFTER VARIOUS TIMES

*Staphylococcus aureus* strain 524SC was grown at 35° C, with shaking, in a 0.1 per cent casein hydrolysate medium supplemented with thiamine, nicotinic acid, 0.5 per cent glucose and 0.002 molar magnesium sulphate until the extinction indicated a dry weight of 0.08 mg/ml. Methicillin, sufficient to give 2  $\mu$ g/ml., was added to four of the five flasks. At the times indicated after this, sufficient chloramphenicol was added to give a concentration of 50  $\mu$ g/ml. Samples were taken after 50, 110 and 320 min, diluted in saline and plated on Hedy-Wright agar. The number of colonies on appropriate plates was counted after 18 h of incubation at 35° C.

\* Time of total growth of culture after inoculation. Methicillin was added immediately after the 50 min sample had been taken and chloramphenicol 15, 30 and 60 min after this time.

shown in Fig. 2. When chloramphenicol is present from the beginning, together with growth-inhibitory concentrations of methicillin, there is a slow increase in the amount of mucopeptide. In the absence of chloramphenicol and the presence of penicillin there is an increase for a period of 90 min, but this is followed by a rapid decrease. This phenomenon can be explained when it is remembered that, in the absence of chloramphenicol, mucopeptidases would continue to be formed at the normal rate, whereas the activity, but probably not the formation, of one of the enzymes that biosynthesizes mucopeptide is inhibited considerably. The ratio of the amount of hydrolytic enzyme to the amount of mucopeptide in the walls therefore increases as the cells grow. Consequently the proportion of the total mucopeptide that is removed in unit time

Fig. 1. The effect of time of addition of chloramphenicol after methicillin on lysis of *Staphylococcus aureus* strain 524SC. The casein hydrolysate medium of the organisms was as given in the legend to Table 1. The dry weight of bacteria was estimated from the extinction measured with an absorptiometer and the use of a calibration curve. The time given on the abscissa is the time in minutes after lysis began (that is, 2 h after the addition of methicillin). The concentration of methicillin was 2  $\mu$ g/ml., and of chloramphenicol 50  $\mu$ g/ml. ●, No chloramphenicol; □, 60 min; ▲, 30 min; ○, 15 min.

Fig. 2. The effect of methicillin on the synthesis of mucopeptide in the presence and absence of chloramphenicol. The conditions for growth of the organisms were as given in the legends to Table 1. Methicillin (2  $\mu\text{g}/\text{ml.}$ ) and chloramphenicol (50  $\mu\text{g}/\text{ml.}$ ) were added to the appropriate flasks when the bacteria had grown to a density equivalent to 0.06 mg/ml. Mucopeptide was estimated chemically by the method described in the legend to Table 2.  $\circ$ , Chloramphenicol only;  $\Delta$ , methicillin only;  $\bullet$ , methicillin and chloramphenicol.

increases as the culture is incubated. The situation obtaining when no further mucopeptidase can be formed in the presence of methicillin is described in Table 2, which shows the effect of increasing concentrations of methicillin on mucopeptide formation by organisms incubated continuously in the presence of chloramphenicol. In this experiment mucopeptide formation was measured both chemically, which gives the net increase or decrease in the total amount of material, and by incorporation of  $1\text{-}^{14}\text{C}$ -glycine, which gives an indication of the total synthesized. It will be seen that 5  $\mu\text{g}/\text{ml.}$  of methicillin is just sufficient to prevent an increase in the amount of mucopeptide (measured chemically). The incorporation of radioactivity, however, shows that about 15.4  $\mu\text{g}$  of mucopeptide/10 ml. of culture were still formed. This would represent an increase of about 50 per cent over the original amount present, but an approximately equal amount has been removed by the mucopeptidase with the result that the total amount remains constant. This calculation, of course, assumes, without evidence, that both new and pre-existing mucopeptides are equally susceptible to the mucopeptidases. Chemical examination of the mucopeptide formed in the presence and absence of methicillin showed no analytical differences in the proportions of the amino-acids. In other words, the mucopeptide in the walls is "turning-over" in these conditions.

Table 2. INHIBITION OF MUCOPEPTIDE SYNTHESIS BY METHICILLIN ACTING IN THE PRESENCE OF CHLORAMPHENICOL

Concentration of methicillin ( $\mu\text{g}/\text{ml.}$ )	Mucopeptide synthesis chemical measurement ( $\mu\text{g}/10\text{ ml.}$ of culture)	percentage inhibition	Radioactive measurements in mucopeptide preparations Total counts $\times 10^{-3}$ in 10 ml. of culture	Mucopeptide synthesized (calculated) ( $\mu\text{g}/10\text{ ml.}$ of culture)
0	7.4	—	6.55	—
5	— 3	100	1.35	15.4
10	— 11	(100)	0.52	5.9
20	— 14	(100)	0.03	0.5
50	— 17.5	(100)	0.01	0.5

*Staphylococcus aureus* strain 524SC was grown at  $35^\circ\text{C}$ , with shaking, in a 1 per cent casein hydrolysate medium supplemented by thiamine, nicotinic acid, 0.5 per cent glucose and 0.002 molar magnesium sulphate until the extinction of the culture corresponded to 0.06 mg/ml. At this point sufficient sterile solutions (1 mg/ml.) of chloramphenicol and methicillin were added to give respectively 50  $\mu\text{g}/\text{ml.}$  and the concentrations shown in the first column above. Sufficient labelled glycine was added to give 0.01  $\mu\text{g}/\text{ml.}$  Samples of 10 ml. were removed immediately into 0.5 ml. of 50 per cent trichloroacetic acid, and again after 2 h incubation with shaking. Mucopeptide was prepared (ref. 18), and one sample of the final preparation was counted in a scintillation counter by suspending the preparation directly in the scintillation fluid. Another sample was hydrolysed in a sealed ampoule overnight with 6 normal hydrochloric acid at  $105^\circ$ . After removal of the hydrochloric acid and solution of the residue in water, the concentration of total ninhydrin-reacting material was measured (ref. 19). The amount of mucopeptide present in a 10 ml. sample at the time of addition of the antibiotic (that is zero time in the culture) was 39  $\mu\text{g}$ .

As the concentration of methicillin is increased, the synthesis side of the balance is gradually decreased until, at a concentration of 20  $\mu\text{g}/\text{ml.}$ , no significant incorporation of carbon-14 from glycine occurs, and in this experiment the full decrease of about 15–17  $\mu\text{g}/\text{sample}$  in the amount of mucopeptide is expressed. Despite removal of mucopeptide, neither death nor lysis of the bacteria occurs in an incubation period of 9 h. A chaser type of experiment in the presence of methicillin, in which a pulse of labelled glycine was followed by an excess of unlabelled glycine, showed that the radioactivity could be removed again from the walls of bacteria incubated in the presence of 2  $\mu\text{g}/\text{ml.}$  of methicillin, as would be expected if "turn-over" were taking place.

It must be presumed that penicillin does not, as part of its primary effect, prevent the synthesis of the enzymes which biosynthesize mucopeptide as distinct from inhibiting their action. The concentration of a penicillin which is just sufficient to kill a micro-organism might then be expected to be that which will inhibit mucopeptide synthesis in a growing culture for long enough to allow the increasing proportion of the polymer removed by the mucopeptidase in a given time to cause irreversible damage to the wall and hence to the membrane underneath. The quicker the organisms grow, the steeper will be the increase in the proportion of hydrolytic enzyme (mucopeptidase) to its substrate (mucopeptide) in the walls, as long as the action of the biosynthetic enzyme remains inhibited. The rate of death of the bacteria, therefore, will be related to the rate of protein biosynthesis in the culture which, in turn, controls the rate of formation of the hydrolytic enzymes.

This hypothesis suggests that cells would die the more rapidly the higher the concentration of the penicillin and the more complete the inhibition of mucopeptide synthesis, as long as the rate of protein biosynthesis remained constant. Methicillin, however, like benzylpenicillin, acting on some strains<sup>14,15</sup> but not others (O'Grady and Pennington—personal communication), has an optimal concentration (1–2  $\mu\text{g}/\text{ml.}$ ) for the rate of killing of *Staphylococcus aureus* strain 524SC, although again some other strains of *Staph. aureus* do not show this phenomenon<sup>16</sup>. The rate of lysis of strain 524SC of staphylococcus is also optimal at about 2–5  $\mu\text{g}/\text{ml.}$  (see Fig. 3). Nevertheless the experiment shown in Table 2 and a number of other results obtained suggest that concentrations of methicillin much greater than 2  $\mu\text{g}/\text{ml.}$  do not inhibit the action of the mucopeptidase.

Fig. 3. The effect of various concentrations of methicillin on the growth and lysis of *S. aureus* strain 524SC. The organisms were grown at  $35^\circ\text{C}$ , with shaking, in the supplemented casein hydrolysate medium (see legend to Table 1). When growth reached a density equivalent to 0.06 mg/ml. the various concentrations of methicillin were added and samples removed during incubation at  $35^\circ\text{C}$  with shaking. The extinction was measured in an absorptiometer and the dry weight was calculated from a calibration curve.  $\Delta$ , 6  $\mu\text{g}/\text{ml.}$ ;  $\square$ , 1  $\mu\text{g}/\text{ml.}$ ;  $\blacktriangle$ , 20  $\mu\text{g}/\text{ml.}$ ;  $\bullet$ , 10  $\mu\text{g}/\text{ml.}$ ;  $\circ$ , 2  $\mu\text{g}/\text{ml.}$

The presence of chloramphenicol throughout the incubation of the organisms with methicillin prevents, or almost prevents, lysis of growing bacteria in the presence of 2  $\mu\text{g/ml}$ . of the penicillin but, from the results in Table 2, allows some action of a mucopeptidase up to a concentration of 50  $\mu\text{g/ml}$ .

Permeability changes in the outer layers of growing staphylococci, like the rate of death and lysis, are at a maximum when the organisms are growing in 2  $\mu\text{g/ml}$ . of methicillin in the absence of chloramphenicol (see Fig. 4). The results recorded in Fig. 4 were obtained 2 h after the addition of methicillin, at about the time that measurable lysis starts in the medium containing 2  $\mu\text{g/ml}$ . of methicillin (see Fig. 3). With this concentration of antibiotic, changes in permeability were just perceptible 15 min after its addition, were marked after 30 min, and the bacteria were completely permeable after about 2.5 h. The optical density of the culture was still increasing after 30 min. The increase in permeability with time occurred exponentially for the first 2 h, which is consistent with the continued exponential production of a mucopeptidase.

The higher concentrations of methicillin do not inhibit the activity of the autolytic enzyme normally present in the wall (see Table 2), and so some other reason for the inhibition of lysis must be sought. Three explanations seem possible. (1) The higher concentrations of methicillin themselves or the intermediates of mucopeptide synthesis which accumulate to a higher concentration as a result of the more complete inhibition of cell wall synthesis may specifically inhibit the formation of mucopeptidase. (2) A concentration of 2  $\mu\text{g/ml}$ . of methicillin is not sufficient to stop mucopeptide synthesis, so that disorganized expansion of the cell wall can occur during turnover. Both the deposition of new mucopeptide and the action of the lytic enzyme during this process may be localized. More damage may be caused than with higher concentrations of methicillin where the synthesis is completely stopped. (3) Higher concentrations of methicillin have some unrelated effect in preventing access of the mucopeptidase to its substrate. There is insufficient evidence to allow us to distinguish between

Fig. 4. The effect of methicillin concentration on the permeability of staphylococci to 8-anilino-1-naphthalene sulphonic acid (ANS). *Staphylococcus aureus* strain 524SC was grown to a density equivalent to 0.06 mg/ml. in the supplemented casein hydrolysate medium and the various concentrations of methicillin added. Incubation with shaking was then continued for 2 h. At the end of this time samples (10 ml.) were taken, the organisms centrifuged out rapidly and resuspended in 1 per cent buffered casein hydrolysate warmed to 35° C. An absorptiometer reading was taken for each sample and 0.5 ml. of 1.0 molar ANS in water added. The solutions were then read on a fluorimeter at 470 m $\mu$ , using light of 400 m $\mu$  to activate the fluorescence. The readings obtained were corrected for scatter from a calibration curve prepared from suspensions of untreated organisms of known extinction. Finally the reading after correction was compared with a similarly corrected reading for a sample of cells of the same density grown in the absence of penicillin and kept at 100° C for 5 min before the addition of ANS solution. Such cells are taken as 100 per cent permeable. This technique was adapted from the one used by Strange and Postgate (ref. 20).

the first two hypotheses. The third seems unlikely in view of the removal of mucopeptide which occurs in the presence of chloramphenicol and higher concentrations of methicillin up to 50  $\mu\text{g/ml}$ . (see Table 2). In considering specific inhibition of mucopeptidase formation, it is possible that the muramyl-peptide part of the nucleotide precursors could be end-product type repressors of mucopeptidase formation. Lytic enzymes, for example, might be expected to produce fragments related to these precursors in cells inhibited by penicillin. The second hypothesis also becomes attractive when the very localized formation of mucopeptide in cultures of multiplying cells<sup>17</sup> is compared with what appears to be the more general formation over the whole surface of the cell which takes place in cultures in which protein biosynthesis is inhibited<sup>10,11</sup>. If the lytic enzyme is also formed locally in multiplying cells, a little enzyme may be able to do much more local damage to the freshly synthesized mucopeptide than the same amount spread over the whole surface of the cell, as it may be when mucopeptide synthesis is completely stopped. The fact that considerable amounts of mucopeptide can be removed from the walls of the staphylococci incubated in the presence of chloramphenicol and high concentrations of methicillin (Table 2), without death or lysis of the micro-organisms, emphasizes the probability of a local removal in the growing cells.

The above experiments were all made with the single strain of *Staphylococcus aureus* 524SC plus methicillin, but similar although less dramatic results were also obtained with strain Oxford using both methicillin and benzylpenicillin, and some experiments were repeated with strain P 20. It is not necessary, of course, that the secondary reasons for death from penicillins of all species and genera of micro-organisms should be the same. Nevertheless the presence of mucopeptidases is widespread in bacteria, and may indeed be necessary for the growth of their walls<sup>10,11</sup>. The absence of lysis of an organism in the presence of penicillin does not, of course, exclude the involvement of mucopeptidases, especially if this action is localized. Relatively slight damage to the existing wall when synthesis is reduced by the antibiotic may be sufficient to cause great changes in the permeability of the cytoplasmic membrane without lysis occurring, as is shown by comparison of the results in Figs. 3 and 4. It should, in conclusion, perhaps be pointed out that the conditions used in the above experiments are quite different from those used in earlier investigations of mucopeptide synthesis<sup>1-4</sup>. In the earlier experiments conditions were such that little or no protein synthesis would occur even in the absence of chloramphenicol.

I thank Miss Linda Brott and Miss Barbara Logan for technical assistance.

# Reversal of the Action of Penicillin

by

J. H. PENNINGTON  
F. O'GRADY

Department of Bacteriology,  
St. Bartholomew's Hospital, London, E.C.1

Growth curves of *Staphylococcus aureus* suggest that cells remain viable for some time after cell wall synthesis has been inhibited by penicillin

DURING an investigation of the mechanism of production of "persisters"<sup>1</sup> by following the changes in turbidity in a culture of *Staph. aureus* to which penicillin had been added, we found that the staphylococci had to be exposed to the action of the penicillin for a considerable period before lysis of the cells occurred, and for much of this time the action of penicillin was readily reversible.

Previous workers using viable counts as the index of the action of penicillin have indicated that viability is rapidly lost within minutes of exposure to the antibiotic in adequate quantities<sup>2-4</sup>. Many of the metabolic functions of the cells are, however, known to proceed normally for some considerable time after exposure and there is reason to believe that interruption of cell wall synthesis and death and lysis of the cells are separate events. Cell wall synthesis has been shown to continue when growth is inhibited by chloramphenicol, and while addition of penicillin to such cultures inhibited mucopeptide synthesis, it did not bring about death or lysis of the cells (preceding article).

It was found, again using viable counting techniques<sup>3,4</sup>, that staphylococci exposed for as little as 15 min to penicillin underwent a long quiescent phase sometimes lasting 3-8 h before growth was resumed. Yet cell wall synthesis, it seems, may be resumed within 15 min of the termination of a short pulse of penicillin<sup>5</sup>. Our observations show that cell wall synthesis may be interrupted and restored after a much longer period of exposure without affecting the viability of the cells.

A strain of *Staphylococcus aureus* which was sensitive to penicillin (M.I.C. 0.06 U/ml.) originally isolated from a wound swab was used throughout these experiments. This organism was chosen because of its sensitivity to penicillin and because the bactericidal action of the penicillin was readily manifested by lysis of the cells<sup>6,7</sup>.

A pear shaped flask suspended between the photo cells of a photometer contained 35 ml. of nutrient broth and 0.5 ml. of an overnight broth culture giving an approximate concentration of  $1 \times 10^6$  organisms/ml. Arrangements were made to maintain the temperature at 37° C and the culture was continuously stirred.

Solutions of benzyl penicillin were used throughout and were added to the culture chamber in quantities of 0.1 ml. The action of the penicillin was terminated by the addition of Wellcome penicillinase. At the concentrations used, even the largest amount of penicillin used was destroyed in less than 10 min.

The addition of penicillin to the culture chamber before or at the time of inoculation did not completely suppress an increase of turbidity. The staphylococci were able to "grow" for some time in the presence of what, as judged by conventional determination, was an adequate dose of penicillin. The effect was more marked when the penicillin was added in the mid-log phase (Fig. 1). Considerable concentrations of penicillin were required at this time to produce an immediate change in the growth curve.

If the action of the penicillin was terminated by the addition of penicillinase a series of curves was obtained as shown in Fig. 2. The activity of the penicillin had to be maintained for almost 100 min before appreciable lysis occurred. Withdrawal before the end of this critical period resulted in the rapid resumption of growth and the curve quickly resumed its former slope (Fig. 3).

Fig. 1. The effect of penicillin on the growth curve when added in the mid-log phase. ( $\Delta$ ), Control; ( $\square$ ), 3 U/ml.; ( $\nabla$ ), 12 U/ml.; ( $\diamond$ ), 3,000 U/ml.

Turbidimetric measurements have been criticized on the ground that they are influenced by the bloated and apparently inviable spheres which penicillin has been shown to induce.

Cooper<sup>8</sup> has shown that the dry weight of a culture increased for approximately 60 min after exposure to penicillin, but only after this time was a rapid increase in size apparent. It is unlikely that the swelling of the cells giving a false appearance of growth could account for the very regular nature of the growth curve for some time after the addition of penicillin, nor would it be expected that the early addition of penicillinase would so restore

growth as to produce a curve indistinguishable from the normal. Furthermore, a family of curves obtained by our method closely resemble those produced by using oxygen consumption as the index of growth<sup>9</sup>. These results suggest that despite the almost immediate action of penicillin on cell wall mucopeptide synthesis the cells remain viable for some considerable time after cell wall synthesis is inhibited.

That the action of penicillin is so readily reversible is supported by the curves similar to that in Fig. 3 obtained

Fig. 2. The effect on the growth curve of the duration of exposure to penicillin. (○), 30 min; (●), 60 min; (△), 90 min.

Fig. 3. A comparison of the effect of exposure to 3 U of penicillin/ml. for 100 min, and 10 U of penicillin/ml. for 30 min.

from a turbidimetric system measuring the effects of pulses of ampicillin on *Escherichia coli*<sup>10</sup>.

These results further emphasize the disparity in time between the effects of penicillin on cell wall synthesis and those secondary factors which lead to death and lysis of the cells.

## Membrane Active Drugs and the Aggregation of Human Blood Platelets

by  
D. C. B. MILLS  
G. C. K. ROBERTS

M.R.C. Thrombosis Research Group,  
Department of Pharmacology, Royal College of  
Surgeons, Lincoln's Inn Fields, London, W.C.2

The aggregation of human blood platelets is stimulated by ADP and other materials, and is known to take place in two stages. Studies with chlorpromazine, imipramine and related compounds indicate that they affect the second stage

HUMAN blood platelets can be made to aggregate by the addition of adenosine diphosphate (ADP), adrenaline, 5-hydroxytryptamine, thrombin and collagen, as well as by other agents (for review, see ref. 1). ADP is released from platelets by fatty acids<sup>2</sup>, thrombin<sup>3</sup> and collagen<sup>4</sup>, and the aggregation that they produce is inhibited by enzymes which remove ADP from the plasma<sup>5</sup>. These enzymes also inhibit aggregation by adrenaline and 5-hydroxytryptamine which, therefore, apparently act

through ADP released from the platelets. Macmillan<sup>6</sup> has observed that, in some samples of human citrated plasma, platelet aggregation occurred in two phases and he suggested that the added ADP caused the release from the platelets of more ADP which was responsible for the second phase. Haslam<sup>7</sup> has additional evidence that supports this conclusion.

Many drugs including antihistamines, local anaesthetics, tranquillizers and antidepressants in high concentrations

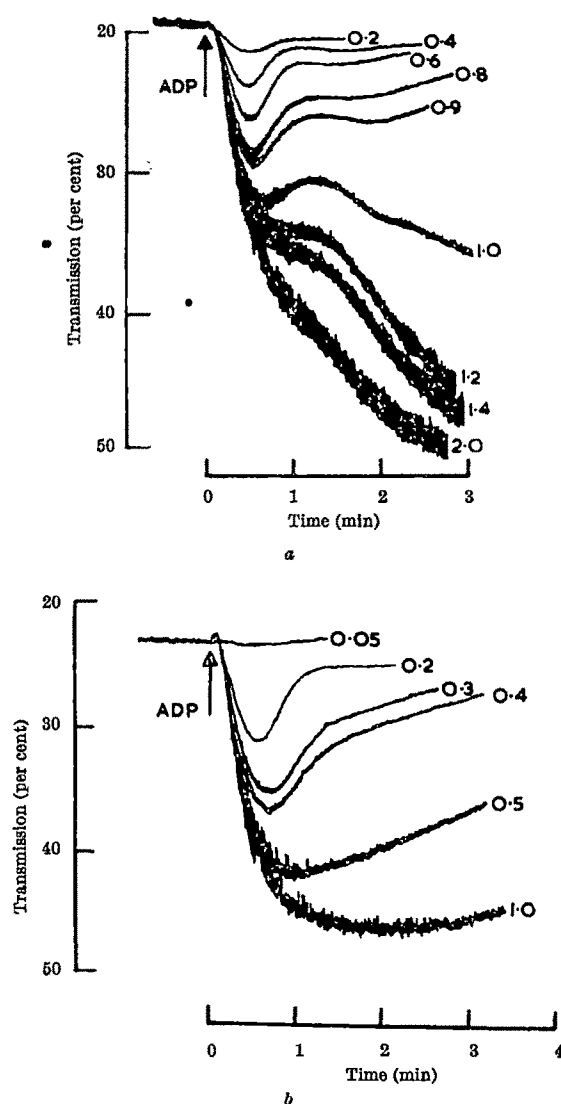

Fig. 1. Aggregation of platelets by ADP in platelet-rich plasma with (a) citrate or (b) heparin as anticoagulant. ADP was added at the arrow to give the final concentrations ( $\mu\text{moles/l.}$ ) shown by each curve.

(0.2–2 mmol/l.) inhibit the aggregation of human platelets by ADP (ref. 7). Promethazine inhibits the aggregation of rabbit platelets by 5-hydroxytryptamine at a much lower concentration (35  $\mu\text{moles/l.}$ ) (ref. 8). More recently, Ryšánek *et al.*<sup>9</sup> showed that aggregation of human platelets by adrenaline and by ADP can be inhibited by antidepressant drugs of the imipramine type at 50  $\mu\text{moles/l.}$  By using the turbidimetric method of Born<sup>10</sup> to follow aggregation continuously, we have established that these drugs at low concentrations act exclusively on the second phase. Some of the results have been reported briefly<sup>11</sup>.

Blood was obtained from healthy volunteers by venipuncture and collected in plastic centrifuge tubes containing 0.1 volume of a 3.8 per cent solution of trisodium citrate or 0.01 volume of a heparin solution (1,000 U/ml. saline). The blood was centrifuged at room temperature for 10 min at 226*g* to obtain platelet-rich plasma which was kept in siliconized glass vessels at room temperature. A sample of 1 ml. was pre-warmed to 37° C for 5 min and placed in a siliconized glass tube in a temperature controlled cell compartment of a modified EEL long cell absorptiometer similar to that used by Haslam<sup>2</sup> but stirred from below with a magnetic stirrer. Light transmission was recorded continuously on a 'Vitatron' 10 mV

recorder at a chart speed of 3 cm/min. The recorder scale was calibrated by setting the absorptiometer to 100 per cent transmission with each platelet-free plasma and adjusting the zero and sensitivity to give full-scale deflexion between 10 and 60 per cent. Reagents were added with microsyringes in volumes of up to 50  $\mu\text{l.}$

Fig. 1 shows superimposed the aggregation traces of normal human platelet-rich plasma with several concentrations of ADP, using citrate (Fig. 1a) or heparin (Fig. 1b) as anticoagulant. With citrate, aggregation was clearly separated into two phases with the plasma samples of twenty-seven out of thirty-one donors tested so far. The concentration of ADP at which the separation was seen, however, was highly critical and varied from one donor to the next. In the remaining four samples the traces were similar to those obtained with heparinized plasma, in which it was rarely possible to distinguish the two phases; the usual pattern was that of Fig. 1b.

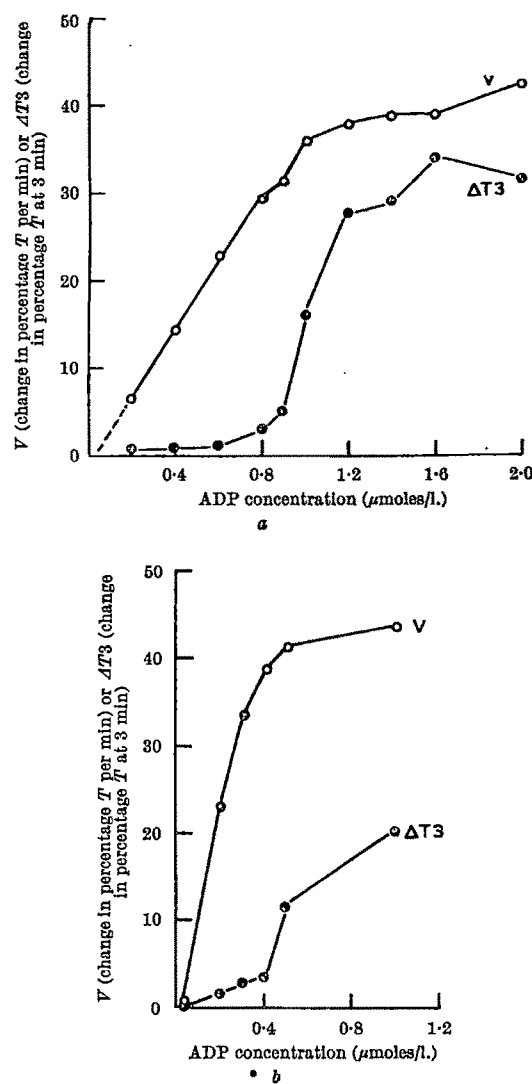

Fig. 2. Concentration-dependence of first phase ( $V$ ) and second phase ( $\Delta T_3$ ) of platelet aggregation induced by ADP in platelet-rich plasma containing (a) citrate and (b) heparin. For definition of  $V$  and  $\Delta T_3$ , see text.

To measure the two phases separately, we chose the initial rate of transmission change ( $V$ ) as an estimate of the first phase and the change in transmission 3 min after the addition of ADP ( $\Delta T_3$ ) as an estimate of the second phase. When the second phase was small, that is, with

low ADP concentrations (Fig. 1b), the initial aggregation reversed within 2.5 min so that by 3 min the contribution of the first phase to the overall effect could be ignored. In Fig. 2,  $V$  and  $\Delta T_3$  are plotted against the concentration of ADP with citrate (Fig. 2a) or heparin (Fig. 2b) as anticoagulant. At a given ADP concentration in heparin plasma the second phase was smaller than in citrate plasma, whereas the first phase was larger. The relation between  $V$  and the concentration of ADP was approximately hyperbolic with a small intercept on the abscissa (representing less than 0.1  $\mu$ molar ADP). By contrast, the plots of  $\Delta T_3$  were sigmoid.

The effect of desmethylinipramine on aggregation by ADP in heparin and citrate plasma is shown in Fig. 3. With citrate (Fig. 3a), low concentrations inhibited the second phase without affecting the first. With heparin plasma, the same concentrations had no effect on the initial velocity but were clearly inhibitory later on (Fig. 3b); this confirms the assumption that the second phase was present although masked by the first phase in the absence of inhibitor.

Adrenaline produced a two phase aggregation which differed from that seen with ADP in that the first phase was slower and did not spontaneously reverse; moreover, the rate and extent of the second phase were independent

Fig. 3. Inhibition by desmethylinipramine of platelet aggregation induced by ADP in platelet-rich plasma containing (a) citrate and (b) heparin. Desmethylinipramine was added, 1 min before the ADP, to give the final concentrations ( $\mu$ moles/l.) shown by each curve.

of the concentration of adrenaline above 2  $\mu$ moles/l.; higher concentrations merely accelerated the onset of the second phase<sup>12</sup> (Fig. 4). Desmethylinipramine (Fig. 5) and the other drugs inhibited both phases of adrenaline aggregation though the effects were much more pronounced on the second phase. The first phase was irreversible, and therefore the two phases were measured by, respectively, the change in transmission ( $\Delta T_1$ ) at the point of inflexion of the curve and the further change ( $\Delta T_3 - \Delta T_1$ ) from this point to the point on the curve 3 min after the addition of adrenaline.

Fig. 4. Aggregation of platelets by adrenaline in platelet-rich plasma containing citrate. Adrenaline was added at the arrow to give the final concentrations ( $\mu$ moles/l.) shown by each curve.

Aggregation by 5-hydroxytryptamine was small, reversible and consisted of one phase only; higher concentrations inhibited<sup>13</sup>. Much lower concentrations of desmethylinipramine and the other drugs inhibited aggregation by 5-hydroxytryptamine than by ADP or adrenaline. All the drugs listed in Table 1 except diphenhydramine completely inhibited at 10  $\mu$ moles/l. the effects of 4  $\mu$ molar 5-hydroxytryptamine; chlorpromazine almost completely inhibited at 1  $\mu$ mole/l.

Suspensions of collagen for producing aggregation were prepared freshly each day by grinding dried collagen (Sigma (London), Ltd.) with saline in a glass mortar and centrifuging the mixture to remove the large particles. Collagen produced irreversible aggregation in a single phase after a lag period which was shortened by increasing concentrations. At 10  $\mu$ moles/l. and greater the drugs prolonged the delay and reduced the maximal rate of the aggregation which sometimes reversed a little; the most active drugs were nortriptyline and amitriptyline. Thrombin at a concentration too low to induce visible fibrin formation (0.1 M.I.H. U/ml.) caused a single-phase reversible aggregation which was not inhibited by chlorpromazine (50  $\mu$ moles/l.) or by desmethylinipramine (20  $\mu$ moles/l.).

Table 1 gives the percentage inhibition by drugs of both phases of aggregation induced by 2  $\mu$ molar ADP or adrenaline. For each aggregating agent the order of activity of the drugs was the same although the absolute inhibitions varied from plasma to plasma. Nortriptyline, amitriptyline and desmethylinipramine were the most powerful inhibitors of aggregation by ADP. Chlorpromazine, however, was as active against adrenaline and more active against 5-hydroxytryptamine.

The results show that chlorpromazine, desmethylinipramine and the other drugs in low concentrations inhibit the second but not the first phase of platelet aggregation by ADP. From their lack of effect on the first phase it appears that the drugs do not influence the mechanism by which ADP aggregates platelets. The second phase of ADP aggregation as well as aggregation by 5-hydroxytryptamine, adrenaline, thrombin and collagen apparently result, as already pointed out, from release of ADP from the platelets. It follows that the drugs probably act by inhibiting this release. Chlorpromazine, diphenhydramine and particularly promethazine have a "stabilizing" action on biological membranes; they inhibit swelling and contraction of isolated mitochondria and ion movements into liver slices<sup>15</sup> and they protect rats against the leakage of cell contents from the liver caused by poisons such as carbon tetrachloride<sup>16</sup>. The phenothiazines inhibit hypotonic lysis of erythrocytes<sup>17</sup>. Desmethylinipramine prevents the depolarization of frog sartorius muscle fibres produced by removal of calcium ions<sup>18</sup>.

Table 1. EFFECT OF DRUGS ON PLATELET AGGREGATION EXPRESSED AS PERCENTAGE INHIBITION OF CONTROLS

Drug	Final concentration ( $\mu$ moles/l.)	ADP (2 $\mu$ moles/l.) $\Delta T_3$	Adrenaline (2 $\mu$ moles/l.) $\Delta T_3 - \Delta T_1$
Chlorpromazine	50	1 (-2-2)	57 (42-68)
	10	6 (3-12)	29 (13-58)
Promethazine	50	-3 (-7-0)	62 (56-68)
	10	-1 (-2-1)	33 (29-37)
Desmethylinipramine	50	11 (1-25)	77 (65-95)
	10	5 (4-6)	53 (44-62)
Nortriptyline	50	-1 (-9-7)	84 (81-87)
	10	-1 (-7-5)	30 (21-39)
Amitriptyline	50	14 (5-27)	69 (45-89)
	10	7 (0-15)	54 (35-74)
Imipramine	50	13 (11-14)	59 (55-62)
	10	4 (1-7)	33 (32-35)
Diphenhydramine	50	5 (-10-14)	35 (25-51)
	10	2 (1-4)	25 (15-36)

$\Delta T_1$  and  $\Delta T_3$  represent the first phase,  $\Delta T_3$  and  $(\Delta T_3 - \Delta T_1)$  the second phase of aggregation (for definition of these parameters, see text). The figures are the mean and range of two to four experiments.

Imipramine and related compounds and, to a lesser extent, chlorpromazine inhibit the uptake of catecholamines by peripheral adrenergic neurones<sup>19</sup>. Both imipramine<sup>20,21</sup> and chlorpromazine<sup>21</sup> inhibit the active uptake of 5-hydroxytryptamine by platelets. This uptake is also inhibited by ouabain<sup>22</sup> which, we have found, does not inhibit aggregation by 5-hydroxytryptamine, ADP or adrenaline. This lack of effect indicates that the mechanism of action of chlorpromazine and imipramine on platelet aggregation is not related to inhibition of amine uptake or of the "sodium pump".

If the drugs act by inhibiting the release of ADP from platelets, their lack of effect on aggregation induced by thrombin implies either that it causes aggregation independently of ADP (ref. 23) or that it releases ADP by a different mechanism. Thrombin<sup>24</sup> and collagen<sup>14</sup> both cause degranulation of platelets but only aggregation by collagen is inhibited by chlorpromazine, etc. If both thrombin and collagen produce aggregation through degranulation, then they must do this in different ways.

If platelets release ADP when they aggregate, this could be the chain reaction postulated by Born<sup>25</sup> to account for the rapid growth of platelet aggregates into haemostatic plugs or thrombi. The low concentrations at which chlorpromazine and desmethylinipramine cause inhibition of

the second phase of platelet aggregation suggest that this effect may be produced *in vivo* in patients receiving these drugs. The inhibition of ADP release by drugs may be effective in the treatment of thrombotic conditions if compounds of this type can be found which produce no serious side effects on the nervous system.

Fig. 5. Inhibition by desmethylinipramine of platelet aggregation induced by adrenaline. The desmethylinipramine was added 1 min before the adrenaline to give the final concentrations ( $\mu$ moles/l.) shown by each curve.

We thank the employees of H.M. Land Registry for generously giving blood; Geigy U.K., Ltd., Eli Lilly and Co., and Roche Products for gifts of drugs; and the Science Research Council for a research studentship awarded to G. C. K. R.

## Pulse Labelled RNA associated with Ribosomes in *Escherichia coli*

by  
MICHAEL ARTMAN  
NITZA SILMAN

Pulse-labelling studies involving sucrose gradient centrifugation in changing concentrations of magnesium ions have been used to demonstrate that newly synthesized RNA, contrary to the current view, is not reversibly bound to 70S ribosomes but is attached even in low concentrations of magnesium ions to both 50S and 30S ribosomal sub-units

THE genetic analysis of the *lac* region of *E. coli* suggested the existence of short lived RNA (called messenger RNA) distinct from both ribosomal and transfer RNA (ref. 1). According to Jacob and Monod, genetic information is transcribed into an unstable messenger RNA which becomes temporarily attached to ribosomes where it serves as template for the synthesis of polypeptide chains. This hypothesis encouraged the search for messenger RNA which should be recognized as distinct from ribosomal RNA and in association with pre-existing ribosomal particles. There is evidence for the existence, in normal *E. coli*, of RNA molecules with these properties<sup>2</sup>. The problem was how to detect messenger RNA, which comprises only 2 per cent to 5 per cent of *E. coli* RNA. The solution was based on the assumption that messenger RNA shows a rapid turnover and therefore most of the RNA synthesized during a very short period would be messenger RNA. Growing cells of *E. coli* were pulse labelled with a precursor of RNA for 1/180 of the generation time, the cells were ground with alumina in a solution containing  $10^{-4}$  molar magnesium ions, and the nature of the pulse labelled RNA was investigated. The conclusion that the pulse labelled RNA was messenger RNA was based on two sets of evidence. (1) When bacterial extracts were treated with phenol most of the newly synthesized (pulse labelled) RNA had a sedimentation coefficient of 8S (whereas ribosomal and transfer RNA had sedimentation coefficients of 23S, 16S and 4S, respectively). (2) When the cell free extracts prepared in  $10^{-4}$  molar magnesium ions were subjected to sucrose density gradient centrifugation the 50S and 30S ribosomal sub-units were almost unlabelled and the majority of radioactivity moved with the 14S peak. When additional magnesium was added to extracts in  $10^{-4}$  molar magnesium ions about one third of the label sedimented with 70S ribosomes.

We have attempted a critical analysis of the results obtained by Gros *et al.*<sup>3</sup>, which shows that the data presented are not sufficient for the identification of pulse labelled RNA with messenger RNA.

The evidence that pulse labelled RNA of normal *E. coli* is distinct from ribosomal RNA is based on the finding that after extraction with phenol it sediments at 8S. The size of pulse labelled RNA which is extracted by phenol largely depends on the mode of extraction of nucleic acids. When the nucleic acids are extracted from *E. coli* which has been lysed by sodium dodecyl sulphate, the preparations of pulse labelled RNA contain, besides chains of low sedimentation rate, large components (16S to 30S) (ref. 3). When RNA is prepared by direct extraction of whole cells with phenol in a low ionic environment the pulse labelled fraction contains no small chains, and can be resolved, on methylated albumin columns, into two main components the molecular size of which correspond to sedimentation coefficients of 16S and 23S, that is, the molecular size of pulse labelled RNA was indistinguishable from that of ribosomal RNA<sup>4</sup>.

In view of these observations, it was assumed that the 8S material, originally designated as messenger RNA,

could be a product of the degradation of large molecules. Pulse labelled RNA of normal *E. coli* can be selectively degraded in conditions where the RNA of mature ribosomes is stable. This has been demonstrated both *in vivo* and *in vitro*<sup>5,6</sup>.

The evidence that pulse labelled RNA is messenger RNA is based on the finding that pulse labelled RNA exists free of ribosomes in extracts made in solutions of  $10^{-4}$  molar magnesium ions (sedimenting at 14S–16S) and that a fraction of the pulse labelled RNA sediments with 70S when the concentration of magnesium is raised to  $10^{-3}$  molar. We have already mentioned that the pulse labelled RNA in extracts made in low magnesium may be a degradation product, and so it is possible that the 14S pulse labelled RNA observed in extracts made in solution of  $10^{-4}$  molar magnesium ions is also a degradation product of large RNA molecules. It is important to decide whether or not the 14S pulse labelled RNA is a degradation product. Pulse labelled RNA may be messenger RNA, or ribosomal RNA which has been synthesized during the short period of labelling, or a mixture of both. In order to distinguish between these alternatives, preparations must be used in which the integrity of pulse labelled RNA is preserved.

The profile produced by bacterial extracts in a solution of  $10^{-4}$  molar magnesium ions has a shoulder of radioactivity of 30S, which is largely obscured by the overlapping and diffuse region of radioactivity with a peak at 14S. The radioactivity which sediments at 30S may represent the undegraded fraction of pulse labelled RNA which exists free of ribosomes in low magnesium and becomes attached to 70S ribosomal particles when the magnesium concentration is increased (messenger RNA). It may, however, represent pulse labelled RNA attached to 30S ribosomal sub-units in a low concentration of magnesium. In the latter case, the radioactivity found in 70S ribosomes on increasing the concentration of magnesium would not signify reversible attachment of pulse labelled RNA to ribosomes, but would result from the association of 50S sub-units with the labelled 30S ribosomal sub-units.

The presence in bacterial extracts of a large fraction of a possible degradation product of large molecules of pulse labelled RNA makes the interpretation of the results equivocal. For investigation of the nature of pulse labelled RNA which is associated with ribosomes, a system composed of ribosomes has several advantages over crude bacterial extracts, as long as a significant portion of the pulse labelled RNA sediments with ribosomes. This should be made clear for the following reasons. (a) Only pulse labelled RNA which is attached to ribosomes is considered; (b) the bulk of endonuclease activity present in bacterial extracts remains in the supernatant after the high speed centrifugation which is involved in the preparation of ribosomes; (c) the use of extracts in a solution containing  $10^{-4}$  molar magnesium ions, which may be detrimental to the integrity of pulse labelled RNA, is omitted; (d) if any portion of the pulse labelled RNA becomes degraded to chains of small

molecular size (8S–14S) in the course of the preparation of ribosomes, it would remain in the supernatant and not obscure the picture of pulse labelled RNA attached to ribosomes.

In this communication we present an analysis of pulse labelled RNA which sediments with ribosomes at  $10^{-2}$  molar concentration of magnesium ions. The results show that about 62 per cent of the total pulse labelled RNA sediments with ribosomes at a concentration of  $10^{-2}$  molar magnesium ions and that the pulse labelled RNA associated with ribosomes behaves as if it were an integral part of newly synthesized ribosomes rather than messenger RNA.

*Escherichia coli*, strain B, was grown in the synthetic medium of Davis and Mingioli<sup>7</sup> in a Dubnoff water bath at 37° C, shaken at 100 oscillations/min (the generation time was about 75 min). The cultures were grown overnight with limiting glucose (0.02 per cent) and reached an optical density of 0.07 (as measured in a spectrophotometer at 550 mμ). Overnight cultures were supplemented with 0.2 per cent glucose and the cells were grown for two generations. To 100 ml. of the exponentially growing cells 10 μc. of uracil labelled with carbon-14 were added. After 30 sec of labelling the cultures were made  $10^{-2}$  molar in sodium azide and poured over frozen and crushed  $5 \times 10^{-3}$  molar *tris* buffer, pH 7.4, containing  $10^{-2}$  molar magnesium ions (referred to as *tris*-Mg<sup>2+</sup> buffer). The cells were twice washed by centrifugation and then frozen. The frozen pellet was ground with twice its weight of alumina and extracted with several volumes of the *tris*-Mg<sup>2+</sup> buffer. Alumina and cell debris were removed by centrifugation at 30,000g for 20 min. For preparation of ribosomes the crude extracts were passed through two cycles of centrifugation at 35,000g for 20 min each and the ribosomes were pelleted and washed by two centrifugations in an ultracentrifuge at 150,000g for 60 min each. The final ribosomal pellet was taken up to  $5 \times 10^{-3}$  molar *tris* buffer, pH 7.4, containing the required concentration of magnesium ions. Three to five optical density units of ribosomes in 0.4 ml. of the appropriate buffer were layered on top of 4.4 ml. of linear sucrose gradient (5 per cent to 20 per cent w/v). The sucrose solutions were made in *tris* buffer and contained the specified concentrations of magnesium ions. The gradient was centrifuged at 37,000 r.p.m. for 2 h at 4° (unless stated otherwise). Samples of four drops each were taken. Volumes were made up to 1.0 ml. with the *tris* buffer and the ultraviolet absorption at 260 mμ and radioactivity (precipitable with trichloroacetic acid) were measured.

Table 1. DISTRIBUTION OF PULSE LABELLED RNA IN BACTERIAL EXTRACTS AND RIBOSOMES

Experiment	Preparation	Ribosomes O.D.	Ribosomal fraction (c.p.m.)	Radioactivity At 14S–16S (c.p.m.)	Ribosomal fraction percentage of total	Specific activity of ribosomal fraction
(1)	Cell free extracts	41.80	88,348	61,253	59.0	2.10
	Ribosomes	42.16	74,104	10,890	87.0	1.80
(2)	Cell free extracts	41.55	82,445	46,493	64.0	1.98
	Ribosomes	46.55	85,650	9,100	90.0	1.84

Table 1 shows that when bacterial extracts prepared in  $10^{-2}$  molar magnesium ions are centrifuged in sucrose density gradients containing  $10^{-2}$  molar magnesium ions 59 per cent to 65 per cent of the pulse labelled RNA sediments with 70S ribosomes and the remaining label moves free from ribosomes and sediments at about 16S–14S. The radioactivity which sedimented at 4S was not counted, because it apparently represented the newly synthesized transfer RNA. Specific activity of ribosomes prepared from the extracts was similar to that of the ribosomal fraction of crude bacterial extracts which indicated that in the course of preparation of ribosomes there was no loss of the pulse labelled RNA which was initially associated with 70S ribosomes. The table also shows that the

ribosomes obtained from bacterial extracts at a concentration of  $10^{-2}$  molar magnesium ions are relatively free of the 14S pulse labelled fraction.

The four parts of Fig. 1 show the analysis of sedimentation of ribosomes prepared from *E. coli* pulse labelled with uracil for 1/150 of the generation time. In  $10^{-2}$  molar magnesium ions (Fig. 1A) most of the radioactivity sediments with 70S ribosomes. Fig. 1B shows the profile of optical density and radioactivity of pulse labelled ribosomes in  $2 \times 10^{-3}$  molar magnesium ions. Here about 75 per cent of ribosomes are dissociated into 50S and 30S sub-units and the radioactivity is distributed among all three groups of ribosomes with distinct peaks at 70S, 50S and 30S. There is some difference between the specific radioactivities associated with the different groups of ribosomes; the highest is that of the 30S ribosomal sub-units (about 50 per cent higher than that of the 50S sub-units). Ribosomes run in sucrose density gradients containing  $4 \times 10^{-3}$  molar,  $6 \times 10^{-3}$  molar and  $8 \times 10^{-3}$  molar magnesium ions (not shown in Fig. 1) gave profiles of optical density and radioactivity similar in all respects to that shown in Fig. 1B, the only difference being the proportion of undissociated 70S ribosomes. The higher the concentration of magnesium ions the larger was the proportion of undissociated ribosomes and a correspondingly larger proportion of radioactivity sedimented at 70S.

Fig. 1C shows the analysis of ribosomes with pulse labelled RNA run in  $10^{-3}$  molar magnesium ions. The profile of optical density shows that the ribosomes are mainly dissociated into 50S and 30S sub-units. Of the three distinct peaks of radioactivity, two coincide with the peaks of 70S ribosomes and 30S ribosomal sub-units. The third peak of radioactivity, which at a concentration of  $2 \times 10^{-3}$  molar magnesium ions, sedimented at 50S, in  $10^{-3}$  molar magnesium ions, lags behind the 50S ribosome peak and sediments at about 47S–43S.

In  $5 \times 10^{-5}$  molar magnesium ions (Fig. 1D) the ribosomes are completely dissociated into 50S and 30S sub-units and the distribution of radioactivity differs considerably from that observed at higher concentrations of magnesium ions. Fig. 1D shows that the peak of radioactivity at 50S completely disappeared and that the region of radioactivity became rather diffuse with a peak around 30S and somewhat below it. This was a consistent finding in all our experiments.

We decided to examine in greater detail the sedimentation behaviour of pulse labelled RNA at a concentration of  $5 \times 10^{-5}$  molar magnesium ions. The behaviour at a low concentration of magnesium ions may merely reflect the dissociation of pulse labelled RNA which sediments at 50S at higher concentrations of magnesium ions, while the sedimentation rate of pulse labelled RNA which sediments with 30S ribosomal sub-units remains unchanged when the concentration of magnesium ions is decreased.

To test this interpretation, pulse labelled ribosomes were resolved into 50S and 30S sub-units by centrifugation in sucrose density gradients containing  $2 \times 10^{-3}$  molar magnesium ions (see Fig. 1B), isolated, made  $5 \times 10^{-3}$  molar with respect to *tris* buffer and  $10^{-2}$  molar with respect to magnesium ions and brought down by centrifugation at 60,000g for 18 h. The pellets of the 50S and 30S sub-units with pulse labelled RNA were suspended in  $5 \times 10^{-5}$  molar magnesium ions and run in sucrose density gradients containing  $5 \times 10^{-5}$  molar magnesium ions. The profiles of optical density and radioactivity are shown in Fig. 2. The main results were: (a) in  $5 \times 10^{-5}$  molar magnesium ions the radioactivity associated with 30S ribosomal sub-units is not displaced and sediments at exactly 30S; (b) the radioactivity associated with 50S ribosomal sub-units lags behind the peak of 50S ribosomal sub-units and sediments at about 40S–30S; (c) there is almost no pulse labelled RNA which sediments at a concentration of  $5 \times 10^{-5}$  molar magnesium ions which is free of ribosomal sub-units.

Our experiments demonstrate that: (a) in extracts prepared by grinding with alumina and elution in *tris* buffer containing  $10^{-2}$  molar magnesium ions about 65 per cent of the pulse labelled RNA is associated with 70S ribosomes and the remaining label sediments free of ribosomes; (b) the pulse labelled RNA associated with ribosomes in extracts made in  $10^{-2}$  molar magnesium ions can be quantitatively recovered with the ribosomal fraction prepared from the extracts by high speed centrifugation; (c) the pulse labelled RNA which sediments with ribosomes is not associated with 70S ribosomes as

such, but with both 50S and 30S ribosomal sub-units; (d) the label associated with the 30S ribosomal sub-units sediments at 30S from the concentration of magnesium used; (e) the label associated with 50S ribosomal sub-units sediments at 50S at concentrations of magnesium ions down to  $2 \times 10^{-3}$  molar. At  $10^{-2}$  molar magnesium ions and below it lags behind the 50S ribosome peak and sediments at 47S-30S.

Analysis of sedimentation shows that by lowering the concentration of magnesium ions the pulse labelled RNA

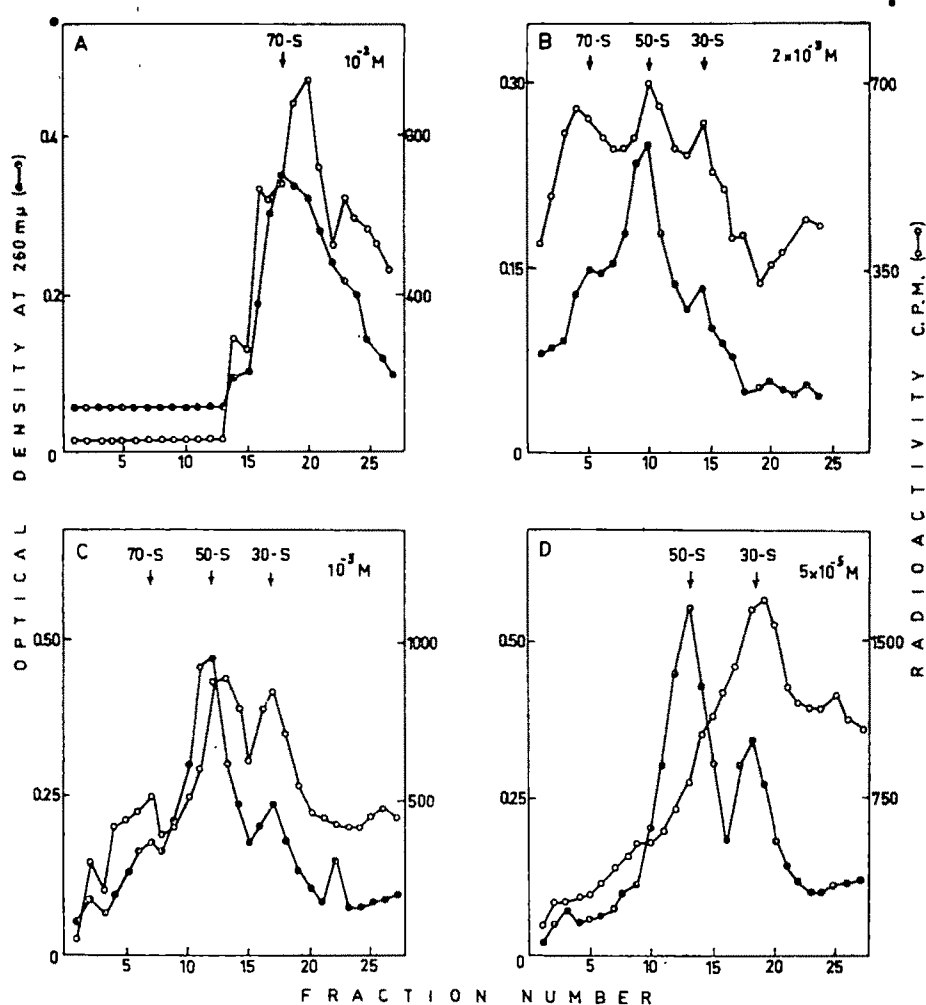

Fig. 1. Sucrose density gradient centrifugation of ribosomes from *E. coli* pulse labelled with uracil for 30 sec. The ribosomes were layered on top of 4.4 ml. of linear sucrose gradient (5 per cent-20 per cent w/w) in 0.005 molar *tris*-hydrochloric acid buffer, pH 7.4, containing magnesium acetate at (A)  $10^{-2}$  molar; (B)  $2 \times 10^{-3}$  molar; (C)  $10^{-3}$  molar; (D)  $5 \times 10^{-5}$  molar. Centrifugation was for (A) 60 min at 37,000 r.p.m., (B, C and D) 120 min at 37,000 r.p.m.

Fig. 2. Sucrose density gradient centrifugation of 50S and 30S ribosomes from *E. coli* after treatment with labelled uracil for 30 sec. The ribosomes were suspended and run in 0.005 molar *tris*-hydrochloric acid buffer, pH 7.4, containing  $5 \times 10^{-3}$  molar magnesium ions. (A) 50S ribosomal sub-units; (B) 30S ribosomal sub-units. Centrifugation was for 180 min at 37,000 r.p.m.

does not dissociate from ribosomes, but sediments with the 50S and 30S ribosomal sub-units. These results can be interpreted in two different ways: (1) the pulse labelled RNA is messenger RNA, but contrary to current ideas it is attached not to 70S ribosomes but to 50S and 30S ribosomal sub-units and it does not dissociate from ribosomal sub-units at a low concentration of magnesium ions; (2) the pulse labelled RNA represents the RNA portion of ribosomal sub-units which are synthesized during the period of labelling.

If the pulse labelled RNA was messenger RNA, its attachment to pre-existing ribosomal sub-units should have brought about an increase in the sedimentation rate of the resulting complexes, so that the slowest peak of radioactivity which represents messenger RNA attached to pre-existing 30S ribosomal sub-unit should sediment between 40S and 50S. The results showing that the pulse labelled RNA associated with 30S ribosomal sub-unit sediments exactly at 30S are most simply interpreted to mean that the pulse labelled RNA represents the RNA portion of the newly synthesized 30S ribosomal sub-units. In the same way, the pulse labelled RNA associated with 50S ribosomal sub-units represents the RNA portion of the newly synthesized 50S ribosomes.

The pulse labelled RNA which sediments at 50S at  $2 \times 10^{-3}$  molar magnesium ions begins to lag behind the 50S ribosome peak in a low concentration of magnesium. The displacement of radioactivity associated with 50S ribosomal sub-units observed at low concentrations of magnesium ions can best be interpreted in terms of conversion of the newly synthesized 50S sub-unit into a ribonucleoprotein particle which sediments more slowly. This interpretation is supported by the finding that mature 50S ribosomes of *E. coli* treated with EDTA could be converted into a component which sediments at 30S (ref. 8). A similar conversion of newly synthesized 50S ribosomal sub-unit seems to be caused by a decrease in the concentration of magnesium ions. 60S ribosome of yeasts can be converted into a 50S ribonucleoprotein particle simply by lowering the concentration of magnesium ions<sup>9</sup>.

The pulse labelled ribonucleoprotein particle which lags behind the 50S ribosomal sub-unit in  $10^{-3}$  molar magnesium ions has all the characteristics of the neosome<sup>10</sup>. Our results indicate that this ribonucleoprotein particle may not be a precursor of the 50S ribosomal sub-unit, but the newly synthesized 50S ribosome itself which becomes converted into a more slowly moving particle at a low concentration of magnesium ions.

It is not surprising that pulse labelled RNA of normal *E. coli* contains newly synthesized ribosomal RNA.

Different methods have resulted in the conclusion that pulse labelled RNA of *E. coli* was made up of 66 per cent of ribosomal RNA<sup>11</sup>. No fraction of the pulse labelled RNA associated with ribosomes which, on the basis of reversible association with pre-existing 70S ribosomes, could be designated as messenger RNA was detectable. If we had analysed the sedimentation behaviour of the pulse labelled RNA in two concentrations of magnesium only (in  $10^{-2}$  molar and  $5 \times 10^{-3}$  molar) we could have interpreted the results in terms of messenger RNA and would not have suspected that the pulse labelled RNA was associated with both 50S and 30S ribosomal sub-units. The evidence that the pulse labelled RNA associated with ribosomes is an integral part of newly synthesized ribosomes was provided by the analyses carried out in magnesium concentrations which were intermediate between the two extreme ones and by analysis of ribosomal sub-units with pulse labelled RNA isolated by sucrose density gradient centrifugation.

There is no direct evidence for the existence in normal *E. coli* of RNA molecules distinct from ribosomal RNA and reversibly attached to pre-existing 70S ribosomal particles depending on the concentration of magnesium ions.

The currently favoured view is that messenger RNA binds ribosomes into polysomes<sup>12,13</sup>. In bacterial extracts prepared by grinding with alumina no polysomes can be detected and the ribosomes exist in the form of monosomes. The reason for this is unknown. The evidence for the existence of polysomes in *E. coli* was provided by the use of gently lysed spheroplasts<sup>14</sup>. It is possible that the pulse labelled RNA which exists free of ribosomes in extracts made in  $10^{-2}$  molar magnesium ions represents messenger RNA which is unable in these conditions to attach to ribosomes and therefore to bind them in polysomes.

## Substrate Hydrophobic Groups and the Maximal Rate of Enzyme Reactions

by  
BAREND H. J. HOFSTEE

Palo Alto Medical Research Foundation,  
Palo Alto, California

The maximum rate ( $V_m$ ) of certain enzyme reactions is increased as much as two to three times by a single additional carbon atom in a "chemically inert" hydrophobic region of the substrate molecule

THE rate of non-enzyme hydrolysis of a series of *n*-fatty acid esters of *m*-hydroxybenzoic acid is not influenced by the length of the acyl carbon chain between  $C_4$  and  $C_{10}$  (ref. 1). Apparently, the electronically insulated and relatively chemically inert carbon chain does not affect the ester bond. Nevertheless, the maximal rate ( $V_m$ ) of hydrolysis of these esters by various esterases usually increases with the length of the acyl carbon chain up to a certain length of chain and most often drops

sharply thereafter<sup>1-5</sup>. This "optimum" length is determined by the acyl moiety of the substrate<sup>3,6</sup> and is specific for each esterase tested. Below the optimum, however, the rate increase for each carbon atom is of the same order (by a factor of between two and three) for enzymes as different as liver esterase<sup>1</sup> and chymotrypsin<sup>3,6</sup>.

These observations indicate that, in contrast to non-enzyme hydrolysis, the "chemically inert" carbon chain plays an important part in hydrolysis by enzymes. Of

particular importance for the present discussion is the fact that the length of the carbon chain invariably affects  $V_m$ . On the other hand,  $K_M$  is not always affected. For example, with liver esterase  $V_m$  increases by a factor of between two and three for each additional carbon atom up to at least  $C_{10}$ , but there is little or no effect on  $K_M$  (ref. 1). As has been shown previously<sup>8</sup>, this indicates that  $K_M$  is a dissociation constant ( $k_{-1}/k_2$ ) and that  $k_2$  is the rate limiting constant for the overall reaction written as

Thus, the length of the carbon chain of the substrate influences the rate at which the products ( $P_1$ ,  $P_2$ ) are formed from the enzyme-substrate complex ( $ES$ ) but has little or no influence on the affinity of the substrate for the enzyme. Perhaps in this case the contribution of the acyl moiety to the affinity of the whole substrate molecule for the enzyme is negligible compared with that of the non-acyl moiety.

The quantitatively similar effect of the length of the carbon chain (below the optimum) on the  $V_m$  constant of different esterases suggests that a common underlying principle is involved. This principle must be sought in "physical" properties of the esters rather than in "chemical" properties because the former (for example, melting point) are influenced by the length of the carbon chain to a greater extent than the latter (for example, the rate of non-enzyme hydrolysis).

Because the rate of non-enzyme hydrolysis of the esters is not affected by the length of the carbon chain beyond  $C_3$ , it appears that the relative rates ( $V_m$ ) of enzyme hydrolysis of a homologous series of substrates  $>C_3$  depend only on the size of the hydrophobic group. A tentative explanation for the large effect of a single carbon atom on the rate of the enzyme reaction and for the occurrence of an optimum length of the carbon chain could be based on the assumption that the hydrophobic acyl group of the substrate enters into association with a particular hydrophobic region in the active centre of the enzyme. (Direct evidence has already been presented for the occurrence of such a region in chymotrypsin<sup>7,8</sup>.) In a hydrophilic environment the largest possible number of substrate carbon atoms could be expected to enter into association with such a hydrophobic region of the enzyme. Only the hydrophobic moiety of that substrate which contains the maximum number of carbon atoms that could be accommodated by this region would thereby be forced into a fixed position on the protein. Smaller hydrophobic groups as well as larger ones could take different positions with the same number of carbon atoms in contact with the enzyme. Thus the size of the hydrophobic region on the enzyme, which may differ from one esterase to the next, may influence the orientation of the substrate in the enzyme-substrate complex. The closer the correspondence of the size of this region to that in the substrate, the greater would be the restriction on the orientation of the latter. For the case where the deacylation constant ( $k_3$ ) is rate limiting, this would apply to the orientation of the acyl group attached to the enzyme by means of an ester bond. (An effect of the length of the  $n$ -acyl carbon chain on the rate of hydrolysis of acylated chymotrypsin has indeed been observed<sup>9</sup>).

This hypothesis would reduce the problem to the effect of intramolecular "strain" in the enzyme-bound substrates on the rate of the pertaining enzyme reactions (for references and discussion, see first edition of ref. 10). This may be further elaborated by assuming that the carbon chain of the substrate enhances the formation and stabilization of the hydrophobic area in the enzyme formed through juxtaposition of hydrophobic amino-acid

side chains which are remote in the unfolded protein. Depending on the number and the nature of the amino-acid side chains involved, some substrate carbon chains would be too short to stabilize effectively the hydrophobic area. Others would be too large to be limited to the stabilization of that particular protein conformation most favourable for the reaction.

The effect of the length of the carbon chain of the substrate on its affinity for an enzyme has been interpreted on the basis of decreasing solubility with increasing length of the carbon chain<sup>11,12</sup>. Decrease in the solubility of the chain could also affect intramolecular hydrophobic interaction in the enzyme-substrate complex, but could not account for the occurrence of an optimal length of the carbon chain.

Although the size of the postulated hydrophobic area on the enzyme would be only one of the parameters determining the rate of reaction, its importance as one of the determinants for specificity would be indicated by the fact that the optimum number of carbon atoms in a particular homologous series of fatty acid esters differs for different esterases<sup>1-5</sup>. Furthermore, in two series of  $n$ -fatty acids esters with different non-acyl moieties, the same optimum number of carbon atoms is found for a particular enzyme. For example, it has been shown<sup>3,6</sup> that although the absolute maximal rates of hydrolysis ( $V_m$ ) of  $n$ -fatty acid esters of *ortho*- and of *meta*-hydroxybenzoic acid by chymotrypsin are grossly different, for both series of substrates the highest relative  $V_m$  is found with the heptoyl ester. This point is further emphasized by the recent findings of Jones *et al.*<sup>13</sup>, who investigated the rate of hydrolysis by chymotrypsin of a homologous series of  $N$ -acylated amino-acid esters with  $n$ -alkyl side chains ( $R_2$ ). The highest rate of hydrolysis was found for  $R_2 = C_5H_{11}$ . Based on the general formula for chymotrypsin substrates,  $R_1-CH(R_2)-CO-R_3$  (ref. 14), the optimum  $R_2$ -chain of the fatty acid esters (for which  $R_1 = H$ ), is identical with that of the amino-acid esters. Becker *et al.*<sup>15</sup> found that the optimum number of carbon atoms in the  $R_2$ -group is the same with respect to the overall rate of acylation (equation 1a) of chymotrypsin by a series of  $n$ -alkyl substituted phosphonates (where P takes the place of the carbonyl-C in the general formula), as for the overall rate of acylation by fatty acid esters of hydroxybenzoic acid. (The relative overall rate of acylation, as compared with the acylation constant ( $k_2$ ), is given by the relative  $V_m/K_M$  ratios of true substrates<sup>5,9</sup>. The optimum number of C-atoms in the  $R_2$ -group of  $n$ -fatty acid esters, with respect to  $V_m/K_M$ , is 6 as compared with 5 for  $V_m$  (ref. 5). Becker *et al.*<sup>15</sup> found an optimum number of 6 carbon atoms for the  $R_2$ -group with respect to the overall rate of acylation by the  $n$ -alkyl phosphonates.)

In  $N$ -acylated phenylalanine esters which are hydrolysed by chymotrypsin at a high rate<sup>10</sup>, the  $R_2$ -group is represented by  $-CH_2\text{---}$  . For the formation of micelles in solutions of compounds with hydrocarbon chains of varying size, a benzene ring is equivalent to 3-4 straight chain carbon atoms<sup>16</sup>. The formation of micelles like the proposed interaction of the  $R_2$ -group with the enzyme depends on the formation of hydrophobic bonds. Thus in this respect, the size of the  $R_2$ -group in the phenylalanine esters also corresponds approximately to the optimum size of the  $R_2$ -group in the fatty acid esters. On the basis of the proposed hypothesis it is thus conceivable that a chief factor in the relatively high rate of hydrolysis of esters of aromatic amino-acid esters by chymotrypsin is that the size of the  $R_2$ -group of these substrates, in particular those of phenylalanine and tyrosine, corresponds to the size of the postulated hydrophobic area on the enzyme surface. The rate of hydrolysis of acetyl-tryptophan ethyl ester is about ten times less than that of acetyl-tyrosine ethyl ester<sup>10</sup>. Perhaps the tryptophan side chain is too large for the hydrophobic area on the

enzyme and therefore not limited to one particular orientation.

The observation that the optimum size of the  $R_2$ -groups is the same for esters of amino-acids, fatty acids and even of substituted phosphoric acid would suggest that in productive complexes the  $R_2$ -groups of these esters are attached to the same hydrophobic area on the enzyme surface. This, however, does not exclude the possibility that part of the chymotrypsin molecules form unproductive complexes through combination of an  $R$ -group with the "wrong" site on the enzyme<sup>17</sup>. As suggested by Jones *et al.*<sup>13</sup>, this could be the reason for the relatively low  $V_m$  of chymotrypsin with respect to the hydrolysis of the fatty acid esters of hydroxybenzoic acid, that is, the benzene ring in  $R_3$  would tend to combine with the site to which the  $R_2$ -group must be attached for reaction to occur. For the esters of amino-acids, this possibility would be reduced through the presence of the  $R_1$ -group that combines with a corresponding group in the multifunctional enzyme<sup>17</sup>. In fatty acid esters the  $R_1$ -group is absent and these esters, therefore, are merely "makeshift" substrates for chymotrypsin. It may be assumed, however, that true fatty acid esterases (and most other hydrolytic enzymes) are bifunctional in nature, that is, are adapted to bifunctional substrates, and do not require the  $R_1$ -group in the substrate. For such enzymes, the size of the hydrophobic side chains in the substrates would be an even more dominant factor for determining the rate of the reaction than is the case for chymotrypsin.

The effect of substrate hydrophobic groups on enzyme specificity is not limited to the type of enzymes discussed

here. A compilation by Dixon and Webb<sup>10</sup> shows that the rate of the reaction of a large variety of enzymes, including oxidases, depends greatly on the presence and length of  $n$ -hydrocarbon chains in the substrate and most often shows a definite optimum value for a carbon chain of particular length. This emphasizes the general importance of "chemically inert" regions in the substrates. In terms of the proposed hypothesis, it would mean that all these enzymes are endowed with a hydrophobic region in the active site. The optimum length of the carbon chain of the substrate would be related to the size of this region.

## Immunological Relationship between Streptococcus A Polysaccharide and the Structural Glycoproteins of Heart Valve

by

I. GOLDSTEIN  
B. HALPERN  
L. ROBERT

Institut d'Immunobiologie  
de l'I.N.S.E.R.M., de l'Association Claude  
Bernard et du Centre International de  
l'Enfance, 96 rue Didot, Paris 14e

Streptococcal infections can cause rheumatic heart disease. Polysaccharide from group A streptococci may induce the production of antibodies by an animal which then react against its own valvular glycoproteins

THE part played by group A streptococcus in the pathogenesis of rheumatic fever is now generally recognized. The mechanism by which streptococcal infection induces the joint and heart disease, however, has not been resolved. Kaplan's recent investigations<sup>1,2</sup> have suggested that the myocardial lesions may arise from an immunological process which results from the cross-reaction between the streptococcal M protein and some protein constituents of the myocardium.

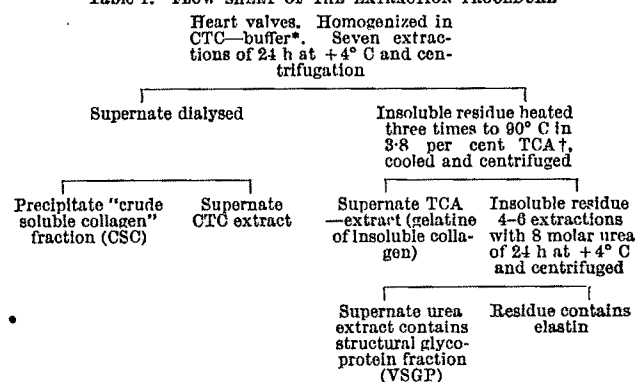

Our investigations tend to indicate that there is a pronounced immunological cross-reaction between the polysaccharide specific to the streptococcus A group and the structural glycoprotein(s) isolated from heart valves.

Valvular extracts were prepared according to the procedure of Robert *et al.*<sup>3</sup> from human and bovine cardiac valves. Human valves were obtained from various heart surgery clinics through the courtesy of Professor Dubost, or were obtained from cadavers within a few hours of death. Bovine valves were obtained from the slaughter house and frozen immediately to  $-20^{\circ}\text{C}$ .

The extraction procedure is depicted as a flow sheet in Table 1. The details of the method have already been re-

ported<sup>3,4</sup>. The structural glycoprotein fraction(s) of heart valves (VSGP) obtained by the urea extraction procedure contains several components; their physical and chemical

Table 1. FLOW SHEET OF THE EXTRACTION PROCEDURE<sup>a</sup>

\* Calcium chloride (1 mole/l.) + tris (0.05 mole/l.), citric acid (0.02 mole/l.) adjusted to pH 7.5.  
† Trichloroacetic acid.

properties will be described elsewhere. The dialysed urea extract precipitates slowly during storage in the cold; however, it can be redissolved in 8 molar urea and redialysed against a 0.9 per cent solution of sodium chloride for use. The structural glycoprotein fractions of other organs, such as aorta, cartilage and cornea, were prepared by the same procedure<sup>3,4</sup>.

Streptococcal extracts were obtained as follows: (1) a trypsinized suspension of group A haemolytic streptococcus, NY 75 strain, was treated with a 0.5 per cent solution of trypsin at pH 8 for 24 h; (2) group A streptococcal polysaccharide was prepared and purified according to the procedure of Fuller<sup>5</sup> and McCarty<sup>6</sup>; (3) group A streptococcal polysaccharide was linked to edestin by diazotization according to the method devised by Hämmerling<sup>7</sup>.

The anti-heart valve antisera used were obtained from rabbits by injecting the total homogenate of the heart valve or its CTC extract (see Table 1). Three 1-ml. injections were given weekly, which contained 5 mg of protein emulsified in an equal volume of Freund's complete adjuvant, for 3 weeks. After a rest for 1 week a booster injection of an equal dose was given and the animals were bled 1 week later.

The anti-streptococcal antisera were obtained by injecting over a period of 3 weeks 0.25 ml. of a suspension of  $10^8$  bacteria in complete Freund's adjuvants in the plantar soles, followed by fifteen daily injections of a water suspension of the bacteria at the same concentration, in progressively increasing dosage, from 0.25–1 ml. After a rest for 8 days, the animals were bled. All immune sera were kept at  $-20^\circ\text{C}$ .

The anti-polysaccharide-destin sera were obtained by injecting 15  $\mu\text{g/kg}$  of the protein-polysaccharide complex in Freund's complete adjuvant three times a week for 2 weeks intramuscularly, followed by three intravenous injections of 20  $\mu\text{g}$  of the complex during the subsequent week. Some animals received a booster injection 10 days later. These sera were tested against the edestin-polysaccharide complex as well as against its separate constituents.

The antibody titres were determined by the quantitative precipitation technique of Kendall-Heidelberger as described by Kabat<sup>8</sup>, using Markham's micro-Kjeldahl procedure<sup>9</sup>, and by a passive haemagglutination reaction using rabbit erythrocytes coupled with antigen by diazotized benzidine as described earlier<sup>10</sup>. The gelose double-diffusion experiments were performed according to a modified procedure using 0.9 per cent agarose plates in a 0.9 per cent solution of saline buffered to pH 6.0. The immunofluorescence experiments were performed according to Coon's direct technique. The gamma-globulin fraction of the antisera was first precipitated at 33 per cent saturation with ammonium sulphate and then labelled with fluorescein isothiocyanate, followed by purification on 'Sephadex G-25' column and fractionation on a DEAE cellulose column according to the technique of Lewy and Sober<sup>11</sup>. The globulins labelled with fluorescein were tested on slides with streptococci of groups A, C, G and H. The specificity of the antisera was tested by absorbing them to the homologous antigen or to antigens to be tested for cross-reactions. The absorptions were performed by adding 5–10 mg antigen as a lyophilized powder/ml. antisera, incubated for 24 h in the cold and

centrifuged. This treatment was repeated three or four times.

All rabbits immunized with the valvular extracts (total homogenate or CTC extract) developed antibodies against several components of the valvular tissue present in the CTC extract (soluble proteins) and in the total homogenate (soluble and insoluble components). All antisera reacted with the structural glycoprotein fraction (urea extract, VSGP) when tested by the haemagglutination and/or precipitation reaction. The titres obtained are indicated in Table 2. The sera obtained by immunization with the urea extract (VSGP) did not give precipitates with this extract in the usual conditions (24 h of incubation at  $+4^\circ\text{C}$ ) but did react in the passive haemagglutination reaction, giving titres between 1/128 and 1/1,256. The weaker antigenicity of the urea extract might arise from the alterations produced by the isolation procedure (see Table 1).

The precipitation and haemagglutination reactions were regularly nullified by previously absorbing the antisera on total valvular homogenates or on the CTC extract. Absorption to the urea extract (VSGP) of either the anti-total homogenate or of the anti-CTC sera reduced their titres by 40–50 per cent. This reduction was accompanied by the disappearance of one of the precipitation lines observed on agarose plates.

All the immunized animals produced antibodies in high titres, ranging from 200 to 1,060  $\mu\text{g}$  nitrogen/ml. serum. These antibodies were entirely absorbed on intact streptococci and also on the purified group A polysaccharide. For the cross-reactivity studies, we used the sera giving the highest titres. Table 3 summarizes the cross-reactions observed between anti-heart-valve antisera and the group A specific polysaccharide. This polysaccharide, when coupled to edestin, precipitates with the anti-valve antisera, giving titres of 25–38  $\mu\text{g}$  nitrogen/ml. serum. When the pure polysaccharide was used somewhat lower titres were obtained. No reaction was obtained with edestin.

Table 3. CROSS-REACTIONS BETWEEN AN ANTISERUM TO TOTAL BOVINE HEART VALVE HOMOGENATE AND THE GROUP SPECIFIC POLYSACCHARIDE OF STREPTOCOCCUS A

Antiserum absorbed to:	Precipitating antibodies to				Fluorescence of group A strepto- cocci treated with fluorescent antiserum	
	$\mu\text{g}$ Nitrogen/ml. of serum †	Strep. Bovine polysacc. VSGP edest.*	No. of lines in double gel diffusion	Strep. Bovine polysacc. VSGP edest.*	Strep. A	Strep. C, G, H ‡
No treatment	114	38	2	1	+++	±
Group A spec. strept. polysacc.	68	0	1	0	±	±
Bovine VSGP	0	0	0	0	±	±

\* Polysaccharide A-destin complex.

† Tested separately with all three strains.

‡ Total precipitate comprising antibody and coprecipitating antigens.

Absorption to VSGP eliminated all the antibodies reacting with the streptococcal polysaccharide. Absorption to the group A polysaccharide did not completely eliminate the reaction with VSGP, but it did eliminate one of the precipitation lines on Ouchterlony plates. The polysaccharide-destin complex also gave a precipitation line with anti-valve antisera which disappeared after absorption on VSGP or on the pure polysaccharide. The antisera labelled with fluorescein reacted specifically

Table 2. PRODUCTION OF ANTIBODIES IN RABBITS IMMUNIZED WITH BOVINE AND HUMAN HEART VALVE EXTRACTS

‡ Precipitate too weak to be determined.

with the group A streptococcus and did not react with the other groups of streptococci tested. This reaction was also abolished by prior absorption of the sera to VSGP, or to the specific polysaccharide. Similar results were obtained with anti-VSGP antisera using the passive haemagglutination reaction: the titres were abolished or considerably weakened after absorption to group A streptococci or to the purified group A polysaccharide.

Absorption to pneumococcus type III specific polysaccharide failed to decrease any titre or to make any precipitation line disappear.

The results of the experiments on the cross-reaction between anti-streptococcal antisera and the structural glycoprotein obtained with bovine heart valve extracts are given in Table 4. Some of the experiments were repeated with human heart valve CTC extracts with essentially identical results. Precipitation reactions were regularly obtained by adding the urea extract of heart valves to anti-streptococcal antisera, giving titres of the order of 30–40 µg nitrogen/ml. serum. This precipitation reaction was abolished by previous absorption of the antiserum to group A streptococci or to the group A specific polysaccharide. The CTC extract of human heart valve also gave precipitates with the anti-streptococcal sera, though in a somewhat lower titre: about 20 µg nitrogen/ml. serum. This reaction was also abolished by previous absorption to group A polysaccharide as well as by the VSGP fraction.

The bovine and human VSGP fraction gave one or two precipitation lines on double diffusion against the anti-streptococcal antisera. These lines disappeared after absorption of the antisera to the VSGP preparation. The precipitation line given by the group A polysaccharide did not disappear after absorption of the anti-streptococcal antisera on to VSGP. This can be explained by the presence of antigenic determinants on the polysaccharide not shared with the preparation of the structural glycoprotein.

Cross-reactions of varying intensity also exist between the structural glycoprotein preparations of various organs<sup>2,4</sup>. The urea extracts of human aorta and of bovine cornea (KGAG) gave cross-reactions with the anti-streptococcal antisera as was demonstrated by the double diffusion method. These precipitation lines disappeared after absorption of the sera to the VSGP fraction.

Absorption to human erythrocytes of blood group A and B did not result in the disappearance of the precipitation lines. The results obtained by specific precipitation and double diffusion were confirmed by the immunofluorescent technique. Fixation of the antiserum labelled with fluorescein to group A streptococci was weakened by previous absorption to VSGP preparations and completely disappeared after absorption to group A streptococcal polysaccharide.

These results clearly demonstrate the existence of common antigenic determinants between streptococcal components, especially the group A specific polysaccharide and the glycoproteins present in the urea extract of heart valves and other tissues (structural glycoprotein fraction).

The immunization of rabbits with human or bovine heart valve extracts regularly induced the production of antibodies against several constituents of this tissue. Some of these antibodies cross-reacted with other tissue

extracts or with serum protein. The cross-reactions obtained between the extracts of several tissues prepared as described here, such as skin, cartilage, cornea, and the polysaccharide of streptococcus A should be emphasized. No cross-reactions, or only very weak ones, were obtained with myocardial extracts. Immunization with total valvular extracts or with the CTC extract yielded anti-VSGP antisera of a higher titre than immunization with the VSGP itself. Nevertheless the VSGP preparation always absorbed one of the antigenic components of the total valvular extract or of the CTC extract. These results are identical with those already reported for the structural glycoprotein of cornea (KGAG)<sup>3</sup>, and are explained by the presence of a soluble "precursor" form of the structural glycoprotein in the soluble fraction of the tissue extract (CTC extract)<sup>12</sup>.

The experiments clearly show the existence of a cross-reaction between antisera obtained by immunization with group A streptococcus or its specific polysaccharide and the structural glycoprotein fraction of heart valves. A significant fraction of the total anti-streptococcal antibody precipitated with the VSGP preparation. On the other hand, the purified group A streptococcal polysaccharide or its edestin complex reacted with the specific anti-VSGP-antisera and with the total anti-valvular antisera, eliminating the anti-VSGP-antibodies. The presence of specific precipitating as well as haemagglutination antibodies was confirmed by the double diffusion and fluorescent antibody techniques. They strongly indicate that the group A specific polysaccharide contains the common antigenic determinant responsible for the cross-reaction with VSGP.

The pronounced cross-reactions obtained with the structural glycoprotein fractions of several types of connective tissue and the weakness or lack of reaction with myocardial tissue tend to indicate that the antigen responsible for the cross-reaction with group A streptococcus is located in the connective tissue of the heart muscle. We obtained evidence strongly in favour of the identity of the structural glycoprotein fraction of heart valves with this cross-reacting antigen. It seems probable that the carbohydrate portion of the VSGP preparation carries the antigenic determinant which cross-reacts with the group specific polysaccharide of the streptococcus. On the basis of these data it is tempting to make the suggestion that the group specific polysaccharide and the structural glycoproteins of the heart play an important part in the production of the auto-antibodies observed in rheumatic heart disease. In this respect it is worth mentioning that recently we were able to demonstrate the presence of antibodies which react with the urea extract of heart valves (VSGP) in the sera of patients with rheumatic disease (to be published).

Thus, in conclusion, immunization of rabbits with extracts from bovine and human heart valves induced the formation of antibody which reacted with several antigens present in these extracts and specifically with a structural glycoprotein fraction extracted with urea (see Table 1). The main interest of the results reported here, however, is the evidence of a cross-reactivity between the valvular structural glycoprotein fraction and group A streptococcal polysaccharide. Group A anti-streptococcal sera were precipitated with the valvular extracts. We think that the cross-reacting antigen is the structural glycoprotein

fraction. Anti-valvular antisera precipitated with group A specific polysaccharide and this cross-reaction was specific for this group of streptococcus. These results suggest that the group A streptococcal polysaccharide, on account of its antigenic relationship with the valvular structural glycoprotein, is involved in the production of the anti-valvular auto-antibodies observed in the sera of patients with rheumatic fever.

## Dietary Retinol and Alpha-Tocopherol and Erythrocyte Structure in Rats

by

O. ROGER ANDERSON  
OSWALD A. ROELS  
R. M. PFISTER

Marine Biology Division, Lamont Geological Observatory, Columbia University, Palisades, New York

The red blood cells of rats deficient in vitamin A become deformed when vitamin E is added to the diet, but are normal in control rats fed vitamin A

Lucy and Dingle<sup>1</sup> investigated the effects of retinol and alpha-tocopherol on rabbit erythrocytes *in vitro*. They showed that erythrocyte membranes are unstable when the cells are incubated in the presence of large amounts of retinol. This treatment causes internal vacuolization of the red blood cell and eventual haemolysis. Addition of alpha-tocopherol to the incubation mixture *in vitro* inhibited this lysis and stabilized the erythrocyte membrane.

Previous work from this laboratory by Roels *et al.*<sup>2</sup> has shown that changes in the stability of the liver lysosomal membrane from rats deficient in vitamin A caused by different dietary levels of alpha-tocopherol can be reversed by dietary retinol: low dietary alpha-tocopherol weakened the liver lysosomal membrane of rats deficient in vitamin A, whereas animals receiving high levels of dietary alpha-tocopherol and no retinol had unusually resistant liver lysosomal membranes. The addition of retinol to the diet brought the stability of the lysosomal membrane back to normal in both groups of animals.

To determine whether this *in vivo* effect of retinol and alpha-tocopherol on the lysosomal membrane is a more general phenomenon, applicable to other biological membranes, we have examined the effect of different doses of dietary vitamin A and vitamin E on rat erythrocytes. Examination with the electron microscope indicates that erythrocytes from rats deficient in vitamin A receiving high or normal doses of vitamin E are swollen and distorted, whereas erythrocytes from pair fed littermate controls receiving normal doses of vitamin A do not show this distortion.

Male albino Sherman rats 21 days old, weighing 40–44 g, were housed in individual cages and fed an experimental diet containing 18 per cent vitamin free casein; 68 per cent glucose; 5 per cent cellulose; 5 per cent peanut oil and 4 per cent Fox and Briggs salt mixture (all percentages by weight). In addition, 2 mg/kg thiamine hydrochloride; 4 mg/kg riboflavin; 4 mg/kg pyridoxine; 1,000 mg/kg choline; 1,000 mg/kg inositol; 300 mg/kg *p*-aminobenzoic acid; 100 mg/kg nicotinamide; 2.5 mg/kg folic acid; 0.05 mg/kg vitamin B<sub>12</sub>; 0.1 mg/kg biotin; 0.042 mg/kg ergocalciferol; 10 mg/kg vitamin K and 10 mg/kg calcium pantothenate were added to the mixture.

Vitamins A and E were administered twice weekly by mouth to the different groups of animals as shown in Table 1. There were ten pairs of animals in each group.

† U.S. Pharmacopeia vitamin A reference standard.

‡ Pure D,L-alpha-tocopherol.

The controls were pair fed with the rats on the vitamin A deficient diet as described previously<sup>3</sup>.

Small samples of whole blood were taken from the tails of the rats, fixed in buffered osmium tetroxide (pH 7.4), washed with distilled water and deposited on grids coated with carbon. After drying at room temperature, the preparation was shadowed with germanium and observed under an electron microscope.

Examination of erythrocytes from rats 3 weeks after starting the experimental diet indicated that the cells from –AE+ rats were distorted as shown in Fig. 1, whereas erythrocytes from the pair fed controls (AE+) were less distorted. Distorted cells in Fig. 1 appear spindle shaped or prolate. Normal cells in Fig. 2 have circular outlines and central depressions.

A frequency count was made using a haemocytometer to determine the proportion of spindle shaped cells occurring in each treatment. Erythrocytes from –AE+ rats contained 43 per cent spindle shaped cells, whereas a sample of erythrocytes from the pair fed control (AE+) contained 24.9 per cent distorted cells. The mean number of cells examined in each condition was 115.

Additional information about the shape of the erythrocytes was obtained using the electron microscope. Erythrocytes from –AE+ rats appear distorted (Fig. 3). The most severe anomaly is represented by spindle shaped cells which cast irregular shadows with undulating margins or sharp peaks. The form of the shadow indicates that some of the spindle shaped cells are folded once; the portion of the cell which has been folded over projects above

the plane of the cell and therefore casts a long and irregular shadow compared with the cells from the pair fed controls (AE+) which are shown in Fig. 4.

In all cases, observations were made over extended areas of the grid and representative clusters of cells were photographed. Even when the least distorted cells obtained from the experimental animals were compared with control specimens there was still a noticeable difference between the two samples.

Observations were subsequently made on blood samples obtained from the same animals at weekly intervals and the degree of distortion increased as the deficiency progressed.

To gain additional evidence about the shape of the spindle shaped cells, clay models of erythrocytes were constructed and observed under oblique illumination from an electric lamp. Patterns of form and shadow similar to those in Fig. 3 were produced by folding models of normal cells along their diameter. When these models were rotated around their axes, shadows were produced much like those in Fig. 3.

Additional measurements were made to determine the size of cells in each experimental treatment. Spindle shaped erythrocytes from rats receiving -AE+ diets had a mean length of  $10.9\mu$  while normal erythrocytes from rats receiving AE+ diets had a mean diameter of  $6.6\mu$ .

Erythrocytes from rats receiving no vitamin A and normal levels of alpha-tocopherol (-AE) appear dis-

Figs. 1 and 2. Photomicrographs of whole erythrocytes fixed in osmium tetroxide. Fig. 1. Erythrocytes from rats receiving no retinol and high doses of alpha-tocopherol (-AE+) showing folded cells (F) which appear spindle shaped ( $\times 900$ ). Fig. 2. Erythrocytes from rats receiving normal doses of retinol and high doses of alpha-tocopherol (AE+). Most cells appear normal with circular perimeters and a central depression ( $\times 900$ ).

Figs. 3-6. Electron micrographs of shadowed whole erythrocytes. Fig. 3. Erythrocytes from rats receiving high doses of alpha-tocopherol and no retinol (-AE+) ( $\times 3,780$ ). Fig. 4. Erythrocytes from the pair fed control rat (AE+) ( $\times 3,600$ ). Fig. 5. Erythrocytes from rats receiving normal doses of alpha-tocopherol and no retinol (-AE) ( $\times 3,125$ ). Fig. 6. Erythrocytes from the pair fed control (AE) ( $\times 3,125$ ).

torted (Fig. 5), much like those from animals receiving high levels of vitamin E and no vitamin A (-AE+).

In this case, however, the distortion is much less severe. Folding of the cells is much less marked than in Fig. 3 and the perimeter of the cells more closely approaches a normal circular perimeter. When these erythrocytes from experimental rats are compared with those receiving normal amounts of vitamin A (AE) it is apparent (Fig. 6) that the latter cells are normal.

In most cases, the cells in Fig. 6 show a central depression and the perimeter is almost circular. These cells closely approximate the biconcave disk of the normal erythrocyte, but the tendency toward swelling and folding is not entirely absent.

Erythrocytes from animals receiving a diet low in vitamin E and without vitamin A (-AE-) or normal doses of vitamin A (AE-) contained slightly distorted cells. In addition to normal cells, abnormal erythrocytes appeared with angular margins and a tendency toward swelling.

The perimeter often appears somewhat angular.

Thin sections of erythrocytes were made from all three experimental conditions reported here. In all cases, no differences in internal structure were observed when erythrocytes from rats deficient in retinol were compared with those from the control receiving normal doses of retinol. No internal vacuoles were observed in any of the sections examined.

These results lead us to conclude that in the absence of dietary retinol, dietary alpha-tocopherol administered

in normal or high doses produces anomalies in the structure of the rat erythrocyte which can be counteracted when normal doses of vitamin A are included in the diet.

The severity of the distortion of erythrocytes from vitamin A deficient rats caused by dietary vitamin E appears to be related to the dose administered; normal doses of alpha-tocopherol result in less distortion than high doses. In both cases, the administration of normal levels of vitamin A inhibits this effect of vitamin E.

At present it is not possible to determine whether the effects of these vitamins result from alterations in the synthesis and development of erythrocytes in the haemopoietic tissue or result from changes in the blood plasma bathing the erythrocytes in the circulatory system.

Low dietary alpha-tocopherol caused slight distortion of the red blood cells, both in the absence and presence of dietary retinol.

These observations provide additional evidence in support of our hypothesis that retinol counteracts changes in the structure and/or function of biological membranes caused by different levels of alpha-tocopherol.

This work was supported by a grant from the National Institutes of Health, U.S. Public Health Service.

## Metabolism of Methylcarbamate Insecticides by the NADPH<sub>2</sub>-requiring Enzyme System from Houseflies

by

M. TSUKAMOTO  
J. E. CASIDA

Division of Entomology and Acarology,  
University of California, Berkeley, California

Certain resistant strains of houseflies are distinguished from susceptible strains by greater enzyme activity for the oxidation of several insecticide chemicals. This may contribute to the mechanism of resistance. Abdomens are a convenient source of this enzyme

THE toxicity of certain insecticidal chemicals is limited by their rapid rate of detoxication in insects. This limitation is often more significant with insecticide-resistant strains, but can frequently be overcome by simultaneous treatment with appropriate synergist chemicals. Repeated exposure of an insect population to an insecticide sometimes selects, as survivors, a strain that is resistant not only to the specific toxicant used and to related agents, but also to some apparently unrelated insecticidal chemicals. While several genetic and biochemical factors are undoubtedly involved in the development of insecticide resistance, one factor is probably the genetic selection of an enzyme system that degrades many types of insecticidal chemicals.

Microsomal enzyme systems are important in limiting the duration of action of drugs in mammals<sup>1</sup>, and many insecticidal chemicals are metabolized to non-toxic or toxic derivatives by the mammalian nicotinamide adenine dinucleotide phosphate (NADPH<sub>2</sub>) system which is reduced by the liver microsomes<sup>2-4</sup>. *In vivo*, insects rapidly carry out many of the same chemical reactions<sup>5,6,7</sup> that occur during incubation of insecticidal chemicals with the NADPH<sub>2</sub> system of liver microsomes. With *in vitro* conditions, however, insect enzyme preparations usually show very low activity in comparison with liver microsomes<sup>8</sup>. NADPH<sub>2</sub> systems of insect microsomes are known to carry out the following reactions (although the yield in reaction products is generally very low): oxidation of phosphorothionates to phosphates<sup>9-11</sup>; oxidation of dimethylphosphoramides<sup>12</sup> and methylcarbamates<sup>13</sup>; hydroxylation of naphthalene<sup>14,15</sup> and DDT<sup>16</sup>; epoxidation of aldrin to form dieldrin<sup>6,17</sup>.

For investigation of the biochemical genetics of resistance in insects to toxic chemicals, there is a need for *in vitro* insect enzyme systems able to degrade many types of insecticidal chemical. Insects readily accomplish such reactions *in vivo*, and so it seemed likely that the enzyme and NADPH<sub>2</sub> system of an insect would meet the need as long as the conditions used are optimal and the system is active when prepared from a convenient species (for example, *Musca domestica* L.); (b) shows differential activity when prepared from susceptible and resistant

strains; (c) acts on a variety of insecticidal chemicals; and (d) is sufficiently active to allow assay of degradation products even when they are prepared from only a few individuals and without extensive enzyme fractionation or purification. Such a system was found in a systematic investigation in which various parts or the entire bodies of adult houseflies were tested, as a source of enzyme with a variety of, for example, co-factors, temperatures, times of incubation, buffer composition, and pH. Various organ systems from adult houseflies were tested, without homogenization, for metabolism of a carbamate insecticide, and the mid-gut was the most active. With homogenates, the highest activity for metabolism of insecticidal chemicals was found with the NADPH<sub>2</sub> system of the abdomen, and this system can be used with or without isolation of the microsome fraction.

Twenty-four insecticides labelled with carbon-14 together with synergists were investigated; nineteen of these were prepared in this laboratory<sup>18-22</sup>. (The insecticides and synergists used are designated by their common or trade names; they are chemically defined either in a later part of this report or in a published list<sup>23</sup>.) The following carbamates labelled with carbon-14 were used as substrates for the enzyme system: 'Baygon' (2-isopropoxyphenyl methylcarbamate); carbaryl (1-naphthyl methylcarbamate), UC 10854 (3-isopropylphenyl methylcarbamate); HRS-1422 (3,5-diisopropylphenyl methylcarbamate); 'Banol' (2-chloro-4,5-xylyl methylcarbamate); 'Mesurol' (4-methylthio-3,5-xylyl methylcarbamate); 'Matacil' (4-dimethylamino-3-cresyl methylcarbamate); 'Zectran' (4-dimethylamino-3,5-xylyl methylcarbamate); 'Isolan' (1-isopropyl-3-methyl-5-pyrazolyl dimethylcarbamate); dimetilan (1-dimethylcarbamoyl-2-methyl-4-pyrazolyl dimethylcarbamate). In most of the experiments, 'Baygon' and 'Matacil' labelled with carbon-14 were used.

For thin layer chromatography silica gel G chromatoplates, 0.25 mm thick, were used. Labelled compounds were detected on the plates by autoradiography, and authentic samples of unlabelled insecticidal chemicals and their metabolites with appropriate chromogenic agents<sup>2,18</sup>. Co-chromatography on thin layers, usually in two dimen-

sions using two different solvent systems, was used for metabolite resolution and tentative characterization. Six housefly strains were studied; these were three laboratory strains (including the SCR-strain<sup>16</sup>), and three strains resistant to carbamate (the Hokota strain which was selected initially for diazinon resistance<sup>24</sup> and later for resistance to 'Baygon', a strain selected with a mixture of carbaryl and synergist, and one selected with 'Isolan'). *L.D.*<sub>50</sub> values ( $\mu\text{g}$  of insecticide/female) were as follows, respectively, for the SCR and Hokota strains: 0.1 and >100 with 'Baygon'; 20 and >100 with 'Matacil'.

Enzyme preparation consisted of homogenization of whole adult flies, or parts of them, in 0.25 molar sucrose and 0.15 molar  $\text{Na}_2\text{HPO}_4\text{--KH}_2\text{PO}_4$  buffer (pH 7.5) in an ice bath using a glass and 'Teflon' homogenizer. In certain cases, differential sedimentation by centrifugation was used to prepare fractions, as follows: nuclei and debris at 800*g* for 20 min; mitochondria at 10,000*g* for 30 min; microsomes at 105,000*g* for 60 min. The soluble fraction was the supernatant which remained after sedimentation of the microsome fraction; the particulate fractions were washed once by resuspension and resedimentation. The concentration of homogenized whole flies, or parts of them, or centrifugal fractions, was usually 10 fly equivalents/2 ml. A typical incubation mixture, in a 25 ml. Erlenmeyer flask, consisted of approximately 0.1  $\mu\text{moles}$  of labelled insecticide or synergist, 5  $\mu\text{moles}$  of  $\text{NADPH}_2$  and 2 ml. of enzyme in the buffered sucrose solution. The substrate was initially added to the flask in hexane solution, the solvent was evaporated, and then the other reaction constituents were added. After incubation for 2 h at 30° C in air with shaking, the reaction mixtures were extracted four times with 10 ml. portions of ether and the components extractable with ether were analysed by thin layer chromatography. The solvent system varied with the labelled materials which were used. For one dimensional chromatography of the labelled methylcarbamates, the plates were developed first with benzene or hexane, to remove certain interfering unlabelled extractives toward the front, and then with one of the following solvent mixtures: ether, hexane and ethanol (77:20:3); benzene and ethanol (9:1); chloroform, ether and ethyleneglycol monomethyl ether (10:1:1); chloroform and acetonitrile (3:1). For two dimensional thin layer chromatography of the carbamates, the plates, which measured 20 cm  $\times$  20 cm, were developed first with the ether, hexane and ethanol (77:20:3) mixture and then with one of the other solvent systems.

Extensive metabolism of labelled 'Baygon' initially was not achieved with homogenates of the whole insect body of laboratory strains and with incubation in the presence or absence of  $\text{NADPH}_2$ . When the body regions were separated, however, the abdomen homogenates gave much greater activity in the presence of  $\text{NADPH}_2$  than did homogenates of the head, thorax or whole insect body. The activity of the abdomen homogenate was greater for any of three resistant strains than for any of three laboratory strains. Assay of centrifugal fractions of homogenate from the abdomen revealed that the activity resides almost entirely in the microsome fraction and that the activity of this fraction is not enhanced by addition of the soluble fraction. The microsomal activity was almost specific for  $\text{NADPH}_2$ ; reduced nicotinamide adenine dinucleotide ( $\text{NADH}_2$ ) was only slightly effective, and the oxidized forms of these cofactors ( $\text{NADP}$  and  $\text{NAD}$ ), flavin adenine dinucleotide, and flavin mononucleotide did not function as cofactors. Although 5  $\mu\text{moles}$  of  $\text{NADPH}_2$  were routinely used, activity was evident with 1–10  $\mu\text{moles}$  of  $\text{NADPH}_2$  and increased when larger quantities were used. Addition of homogenates of the head or the thorax, individually or in combination, to homogenates of the abdomen always resulted in remarkable reduction in the activity of the enzyme system. The biochemical nature of the inhibitory materials was not defined, but they are present largely

in the 800*g* sediment fraction (debris and more inhibitory when obtained from the head, thorax, and are relatively heat stable (c when held in a boiling water bath for 15 min); activity for enzyme systems which metabolize *in vitro* was achieved by using homogenates separated abdomens, or microsomes from separated abdomen homogenates or the whole homogenates as the enzyme source.

Similar findings were obtained for each methylcarbamate insecticide chemicals investigated. Enzyme activity is higher for the resistant susceptible strain, for the abdomen homogenate with the whole body homogenate, and  $\text{NADPH}_2$  as compared with no added  $\text{NAD}$ . Overall relationships are illustrated in Fig. 1, 'Matacil' as the substrate and the Hokota as resistant and susceptible strains, respectively.

Conditions of rearing and handling the fly preparation of enzymes, also affected its results. Great difference in activity was not found between male and female flies and within 1–15 days after emergence of adults, when these adults were fed only sugar; this is at variance with a published report of activity of fly microsome in hydroxylation of increases remarkably during ageing of the adult. Activity was higher for adult flies fed on mill for those fed on sugar and water; it is believed that micro-organisms in the digestive tract are not involved in carbamate metabolism, because flies fed containing 3 per cent penicillin G and 10 per cent streptomycin sulphate (w/v) for 4 days, before homogenization of the abdomens, had the same activity as those not so treated. The housefly enzyme of limited stability on incubation at 37° C, was chosen for incubation and only fresh preparations were used. The enzyme activity of homogenate from the abdomen was largely lost at 5° C or in a frozen state, but the activity of the thorax fraction, when frozen, was stable for this routine investigation, the flies were not sexed and used without anaesthetization 3–7 days after emergence during which period they were fed freely on milk, sugar and water.

A variety of different chemical reactions to the stated conditions, based on the identity of carbamate metabolites which have been tentatively characterized; (a) aromatic hydroxylation occurs at 4- or 5-position of carbaryl; (b) *O*-dealkylation of 'Baygon' to yield 2-hydroxyphenyl methylcarbamate; (c) *N*-dealkylation occurs with 'Matacil' to yield 4-methylamino, 4-amino and 4-formamido derivatives (Fig. 1) as well as the 4-methylformamido derivative 'Zectran' also forms an analogous series of (d) *N*-methyl hydroxylation to form the *N*-hydroxy derivatives occurs with 'Matacil' (Fig. 1) and 'Baygon', 'Banol' and 'Zectran'; (e) sulfoxidation of 'Mesuro' to the corresponding sulfoxide.

The  $\text{NADPH}_2$  system from the fly abdomen was active in the conversion of other types of chemicals and synergists to more polar products indicated by thin layer chromatography and thin layer chromatography. In each case, little if any metabolism without added  $\text{NADPH}_2$ , compared with the addition of  $\text{NADPH}_2$ . Two chlorinated insecticides, aldrin and DDT, and an organophosphorus insecticide, 'Imidan' (*o,o*-dimethyl *S*-phthal phosphorodithioate), were metabolized. 'Matacil', aldrin and 'Imidan', but not DDT, was active when enzyme preparations from the Hokota strain were used. Aldrin yielded primarily dieldrin but also several products, while 'Imidan' gave several metabolites including small amounts of the oxygen analogue as a metabolite. The list of different chemical reactions in the stated conditions can be expanded by a

Fig. 1. Autoradiogram showing *in vitro* production of metabolites of  $^{14}\text{C}$ -matacil by homogenates of whole bodies or abdomens of susceptible and resistant houseflies.

The extraction solvent was ether; the developer for the thin layer chromatogram was hexane followed by a mixture of ether, hexane and ethanol (77 : 30 : 3). Carbon-14 was in the carbonyl position; analogues of

were used with structures as follows:

	A ('Matacil')	B	C	D	E
$\text{R}_1 =$	$\text{CH}_3$	$\text{CH}_3$	$\text{CH}_2\text{OH}$	$\text{CH}_3$	$\text{CH}_3$
$\text{R}_2 =$	$\text{CH}_3$	$\text{CH}_3$	$\text{CH}_3$	$\text{H}$	$\text{H}$
$\text{R}_3 =$	$\text{CH}_3$	$\text{H}$	$\text{CH}_3$	$\text{H}$	$\text{CHO}$

of the identity of metabolites tentatively characterized, as formed from these chemicals: (a) phosphorothionate oxidation converts 'Imidan' to the corresponding oxygen analogue, based on co-chromatography in two dimensions with benzene and ethyl acetate (9 : 1 and 1 : 2); (b) epoxidation forms dieldrin from aldrin, as confirmed by co-chromatography using hexane and hexane-benzene (4 : 1) for the two dimensional development; (c) alkyl hydroxylation of DDT to form dicofol in small yield was indicated (comparisons for metabolite identification based only on  $R_F$  values, in two dimensions, with hexane and carbon tetrachloride). Extensive metabolism also took place with two botanical insecticides, rotenone (unpublished results of Fukami and Casida) and pyrethrin (unpublished results of Yamamoto and Casida) and with three synthetic D-trans-chrysanthemumate esters<sup>22</sup> (the allethrolol ester—allethrin; the 2,4-dimethylbenzyl ester—dimethrin; and the 3,4,5,6-tetrahydropthalimido-methyl ester—phthalthrin). The following six methylenedioxyphenyl compounds, which are active as insecticide synergists, were also metabolized by the NADPH<sub>2</sub> system of the fly abdomen (unpublished results of Esac and Casida): piperonyl butoxide; sulphoxide (two diastereoisomers, separately investigated); myristicin (5-allyl-L-methoxy-2,3-methylenedioxybenzene); safrole; and dihydrosafrole. It is not known whether the conditions which were found to be optimal for 'Baygon' metabolism are also those optimal for metabolism of the aforementioned compounds, or whether one or more

enzymes are involved in metabolizing these varied types of insecticide chemical and synergists.

The activity of the system, using homogenates of abdomens from the Hokota strain, was such that one abdomen (average fresh weight of 6 mg) resulted in significant metabolism of 0.1  $\mu\text{mole}$  of 'Banol', 'Matacil', 'Mesurol', or 'Zectran' when incubated for 1 h; ten abdomens destroyed 0.1  $\mu\text{mole}$  of each of these four carbamates and also destroyed 1  $\mu\text{mole}$  of phthalthrin in 2 h. The activity of the homogenate of the resistant fly abdomen or microsomes is much greater, for destruction of methylcarbamate insecticides, than that of an equivalent fresh weight of rat liver homogenate or microsomes, respectively.

Detoxication processes constitute only one of several mechanisms involved in resistance. In certain cases, the pathway of degradation of insecticides *in vivo* differs from that in a selected *in vitro* enzyme system. Most of the metabolic changes already mentioned involve conversions to products of reduced insecticidal activity, but this is not always the case as, for example, in aldrin epoxidation, phosphorothionate oxidation, and hydroxylation or oxidation of certain substituted-phenyl methylcarbamates<sup>2-4,7,13,28</sup>. It is therefore difficult to generalize on the potential significance of the microsomal-NADPH<sub>2</sub> system as a resistance mechanism.

These enzyme systems from flies should be useful in future investigations of relations between structure, metabolism and toxicity of insecticidal chemicals, as well as of the basis for synergism and the biochemical genetics of resistance mechanisms. It may also be appropriate for comparative biochemical studies on the mechanism of microsomal hydroxylation reactions.

This investigation was supported in part by grants from the U.S. Public Health Service, National Institutes of Health, the U.S. Atomic Energy Commission, and S. C. Johnson and Son, Inc. ## LETTERS TO THE EDITOR

## PLANETARY SCIENCE

## Neutron produced Phosphorus-32 in the Barwell and St. Severin Meteorites

NUCLEAR reactions induced by neutrons in meteorites have been discussed by a number of authors<sup>1-6</sup>. A few radioactive and stable isotopes, produced mainly by thermal and epithermal neutrons, have been measured<sup>7-16</sup>, but there is not much direct information on the flux of fast neutrons ( $E \gtrsim 1$  MeV). The most sensitive indicator of fast neutrons, the phosphorus-32 produced by  $^{32}\text{S}(n,p)$  reactions, has been used only once<sup>11</sup>, partly because of the short half-life of phosphorus-32, 14.3 days. Furthermore, in the one measurement of phosphorus-32, only the activity of the bulk sample was determined, that is, no attempt was made to distinguish between the component produced by spallation and that produced by the  $^{32}\text{S}(n,p)$  reaction.

We were able, through the kindness of Dr. Eva Paneth, Prof. Sylvester-Bradley of the University of Leicester, and Dr. Max Hey of the British Museum, London, to obtain a sample of the Barwell meteorite which fell on December 24, 1965, and were able to measure the amount of phosphorus-32. Details of the experimental procedure used to extract a number of radioactive isotopes from various mineral fractions of the meteorite will be given in a later paper. In this report we wish to give the results for phosphorus-32 only.

Sulphur occurs in normal chondrites predominantly in the form of troilite, so that this mineral will contain the phosphorus-32 produced by the  $(n,p)$  reaction in addition to that from the spallation of the iron in the iron sulphide. In the metal phase, on the other hand, only phosphorus-32 produced by spallation will be present. Thus separate analyses of the two phases should allow the two fractions to be distinguished. Complications, however, must be expected if the troilite and/or the metal phase are extremely fine-grained ( $d \lesssim 1\mu$ ), that is, if their average grain size is comparable with the range of the recoil phosphorus-32. Fortunately, it rarely happens that most of either or both phases occurs in such a way; instead, it is occasionally even possible to separate mechanically large troilite nodules and metal particles in sufficient quantities to allow an accurate determination of the activity of the phosphorus-32.

In the case of the Barwell meteorite, the separation was carried out by fractional dissolution. First, in order to dissolve the metallic iron-nickel, the powdered sample (164.3 g) was treated under vacuum for 2 h with 1.4 l. of an aqueous solution containing 150 g of ammonium-peroxydisulphate. This was followed by a 30 min treatment with 50 c.c. of bromine in 2.5 l. of water which dissolved all the troilite and a small amount of olivine. In the ammonium persulphate step 56 mg of phosphorus carrier were added in the form of ammonium hydrogen phosphate while during the bromine treatment sufficient native phosphorus went into solution, as expected. Table 1 gives the amounts of the relevant elements (and silica) which were dissolved in the two steps. (The calcium to phosphorus ratio found in the bromine fraction supports the idea that in normal chondrites phosphorus occurs as calcium phosphate and not as schreibersite.) In both cases the phosphorus was precipitated as ammonium phosphomolybdate, radiochemically purified and converted to  $\text{Mg}_2\text{P}_2\text{O}_7$ . The chemical yields were 55 per cent for the metal and 81.5 per cent for the troilite. The activity was determined with a

'Sharp' low beta flow counter and followed for several half-lives. As can be seen from Fig. 1, the samples counted were radiochemically very pure. Furthermore, there is no indication of any contribution to the activity from phosphorus-32. Because of the short range of the  $\beta$ -particles, compared with the sample thickness, this is to be expected.

Fig. 1. Phosphorus-32 activities in troilite (black bars) and metal-fraction (open bars) of Barwell and St. Severin as a function of time. The least square fit curves were calculated with a half-life of 14.3 days. The arrows indicate the date of fall of the meteorites.

From the measured activities, extrapolated to the time the meteorite fell (Table 1; last column), and the amounts of nickel-iron and sulphur dissolved, the rates of production of phosphorus-32 from the spallation of iron ( $R_{\text{spall}}$ ) and the  $^{32}\text{S}(n,p)$  reactions ( $R_{n,p}$ ) can be calculated (Table 2).

As we completed these measurements, another stone meteorite—the amphoterite St. Severin—fell on June 27, 1966. Again, we fortunately obtained a suitable sample two weeks after the date of the fall, this time through the prompt and generous support of Dr. Jacques Labeyrie, Centre National de la Recherche Scientifique, Gif-sur-Yvette. In this case a chemical separation of the metal and troilite phase was not necessary as our sample contained some fairly large troilite inclusions which were taken out mechanically. A few grams of metal phase were separated with a magnet. The purpose of measuring the phosphorus-

Meteorite		Iron	Nickel	Sulphur	Calcium	Phosphorus	Silica	(dpm) <sub>t=0</sub>
Barwell	Metal	14.22	1.86	1.38	0.070	—	1.04	1.3 ± 0.6
	Troilite	4.96	—	2.28	0.256	0.130	2.14	2.64 ± 0.26
	Bulk analysis	21.90	1.1	2.24	1.37	0.08	39.35	—
St. Severin	Metal	2.23	0.94	0.045	—	—	0.024	0.25 ± 0.10
	Troilite	2.20	—	1.26	—	—	—	1.10 ± 0.10
	Bulk analysis	22.6	0.59	3.21	—	—	—	—

The amounts of relevant elements and silica dissolved as "metal phase" and "troilite" (in grams). The results of the "bulk analysis" are given in weight per cent. (In case of St. Severin an aliquot of the pulverized sample (170 g) was used for the bulk sulphur analysis. The troilite taken out mechanically before crushing the sample is included in the result.) The last column gives the phosphorus-32 activities in disintegrations per min at the time of fall of the two meteorites.

Meteorite	$R_{n,p}$	$R_{\text{spall}}$	$R_{\text{total}}$
Barwell	1,200 ± 180	-20 ± 40	27 ± 4
St. Severin	780 ± 100	68 ± 40	25 ± 4

The production rates of phosphorus-32 by spallation reactions on nickel-iron ( $R_{\text{spall}}$ ) and due to the  $^{32}\text{S}(n,p)$  reaction ( $R_{n,p}$ ), given in atoms per min and kg of NiFe and S, respectively. In the last column the total activity in disintegrations per min per kg meteorite is listed. In both cases only the contribution due to  $R_{n,p}$  was taken into account. The inclusion of the non-significant  $R_{\text{spall}}$  values would be misleading.

32 in the metal phase was not to determine  $R_{\text{spall}}$  but to make sure that the activity in the troilite comes predominantly from the  $^{32}\text{S}(n,p)$  reaction.

Both samples were dissolved in bromine water, after addition of phosphorus carrier; all further processing was identical to that described above. The chemical yield was 77 per cent for the metal phase and 56 per cent for the troilite. The results for both meteorites show unambiguously that the activities of phosphorus-32 in the troilite phase are produced by  $(n,p)$  reactions on sulphur-32. The values for the rates of production of phosphorus-32 allow some important conclusions. According to Lingenfelter *et al.*<sup>16</sup>, 88 per cent of all neutrons produced in chondritic material are evaporation neutrons with a differential spectrum  $N(E)dE = E e^{-2E/\theta} dE$ , where  $\theta$  is the average energy; the remaining 12 per cent are knock-on neutrons with a differential spectrum  $N(E)dE = \beta E^{-2} e^{-180/E} dE$ . Using these spectra with  $\theta = 3$  MeV<sup>17</sup> and the cross-section data for phosphorus 32 produced by the  $(n,p)$  reaction in the relevant energy region<sup>18-22</sup>, an effective cross-section of  $\sigma(n,p) \sim 130$  mb. is obtained. This together with the  $R_{n,p}$  values of Table 2 yields a neutron flux of 8.2 neutrons/cm<sup>2</sup> sec for Barwell and of 5.2 neutrons/cm<sup>2</sup> sec for St. Severin. (With  $\theta = 2$  MeV the effective cross-section would be  $\sigma(n,p) \approx 70$  mb. and the fluxes correspondingly higher. In both cases the change of the neutron energy spectrum due to the slowing down of the neutrons was neglected, as only a few collisions bring the neutrons below 2 MeV, where the cross-section is already negligibly small.)

These different values do not necessarily reflect a difference in intensity of the cosmic radiation as the neutron flux is especially sensitive to the pre-atmospheric size of a meteorite and the position of the sample within it.

As expected, the production rates of phosphorus-32 from spallation of iron cannot be given with any degree of accuracy, partly because of the small amounts of metal available and the predictably low yield<sup>3</sup>. Furthermore, as metallic nickel-iron is frequently found adjacent to troilite, an appreciable portion of the activity in the metal may be introduced by recoil of phosphorus-32 produced by the  $(n,p)$  reaction from sulphur-32 (see above).

We thank Miss H. Baddenhausen, Miss I. Schöler, Mrs. U. Weidlich and Mr. B. Spettel for technical assistance.

## Ozonesonde for Rocket Flight

It is well known that the vertical distribution of the atmospheric ozone shows marked variations with latitude, season and weather conditions. Ozone measurements had usually been made primarily with balloons using instruments due to Paetzold and Piscalar<sup>1</sup>, Brewer and Milford<sup>2</sup> and Regener<sup>3</sup>, and by a few rocket probes using various types of solar spectrometers<sup>4</sup>. The balloon sondes do not reach the stratopause. Recently, a rocket-borne ozonesonde<sup>5</sup> which utilized the chemiluminescent principle for ozone detection was developed and flown with the *Arcas* rocket at White Sands Missile Range (32° N.), New Mexico. A serious disadvantage of these earlier rocket-borne sondes is that they cannot be fired during daylight because of the effect of stray light on the photomultiplier output. There is a pressing need for an ozonesonde which can be deployed at any time of day.

This rocket ozonesonde, a self-pumping type, consists of three main parts: power supply, sample bottle including photomultiplier tube and chemiluminescent detector, and telemetry circuit. The photomultiplier tube and the associated high voltage supply circuitry are potted in black silicone rubber and mounted inside the bottle, as is shown in Fig. 1. The channel for the flow of air into the bottle is made from 'Teflon' and provides two 90° turns to eliminate stray light. The chemiluminescent detector is mounted across the photomultiplier tube. Ozone in the environment flows over the detector and the photons produced by the destruction of ozone molecules on the chemiluminescent material are monitored by the photomultiplier tube, the output signal from which is transmitted on a carrier frequency of 1,680 Mc/s (ref. 6).

The ozonesonde is deployed from an *Arcas* rocket above the stratopause. The bottle empties itself at high altitude and gases flow into it as the instrument descends on a radar reflecting parachute 15 ft. in diameter. The intensity of the emitted light is directly proportional to the flux of ozone entering the detector, and this in turn is equal to the product of the ozone concentration and the rate of flow. Thus the flow rate into the detector must be known. As the instrument falls through an atmosphere of increasing density, the pressure inside the bottle tends to come into equilibrium with the external pressure, so that the net flow of air (c.c./sec) into the bottle through the inlet channel depends on both the external and internal pressures\* and is equal to

$$\frac{V_i T_a}{P_a T_i} \left| \left( \frac{dP_i}{dt} - P_i \frac{d \ln T_i}{dt} \right) \right|$$

where  $V_i$  is the volume of the bottle;  $T_i$  the air temperature and  $P_i$  the pressure inside the bottle;  $T_a$  the ambient external temperature; and  $P_a$  the ambient external pressure;  $t$  is the time.

This expression can be simplified considerably if one assumes  $P_i = P_a$  and  $T_i = T_a$ . As the instrument falls, the bottle will be cooled continuously, so that the second term, which is an order of magnitude less than the first term, will always add to the flow rate. The ozonesonde is calibrated before launch by the use of an ozone generator<sup>3</sup>. Ozonized air of known concentration is injected into the bottle at a known flow rate and sensitivity is set in the proper range.

The rocket borne ozonesonde\* was flown on June 15, 1966, at 2215 U.T. and deployed at 65 km altitude. Radar tracking of the parachute provided the altitude and rate of fall as the function of time. Ozone concentration was sampled continuously. The results are shown in Fig. 2, as the variation of ozone partial pressure with altitude.

The total ozone measured by the instrument was compared with the measurement taken by Dobson's spectrophotometer at this latitude. The agreement is fairly good.

\* The rate of flow is independent of the characteristics of the inlet because the latter has a large diameter.

### Kink-bands and Related Geological Structures

MARSHALL's renewed criticism<sup>1</sup> of my paper<sup>2</sup> on kink-bands again argues that kink-bands are the exact equivalents of shear planes, at least in terms of angular relationships. In 1964 there was scant experimental evidence for my contention that kink-bands in foliated rocks,

unlike shear planes, tend to form at angles of more than  $45^\circ$  to the direction of the maximum compression<sup>2-4</sup>. Field evidence<sup>2</sup> was considered suspect "in view of the difficulty of locating  $P_{\max}$  in any but a perfectly symmetrical, truly conjugate system of kink-bands"<sup>1</sup>.

The more recent experimental work of Paterson and Weiss<sup>5</sup>, which is of wide implications for structural geology, has now demonstrated conclusively that kink-band and shear-plane systems have different geometries. Specimens of Nelligen phyllite, compressed parallel to the foliation, showed well developed sets of conjugate kink-bands, symmetrical about the foliation. The authors<sup>5</sup> obtained 475 determinations of the angle between the undeformed foliation and the kink-plane (the angle  $\alpha$  of Fig. 4, ref. 2). The mean value was  $58^\circ$  and the variation shown in their histogram is quite small. The result compares well with the modal value reported<sup>2</sup> ( $55^\circ$ - $60^\circ$ ) for natural kink-bands, with the same symmetrical geometry, in the slates of the Ards Peninsula.

It may be that in these results Marshall finds room for application of the hypotheses of second-order shearing, either that of McKinstry<sup>6</sup> (as quoted in his letter of 1964, ref. 3) or that of Moody and Hill<sup>7</sup>. Some other treatment seems desirable. As yet, however, no complete theoretical explanation of the high  $\alpha$  values has emerged. Two suggestions have been offered. Paterson and Weiss<sup>5</sup> cite the work of Taylor<sup>8</sup> on the propagation of faults and write that they "would expect an analogous calculation" to show that in an ideal foliated body compressed parallel to the foliation, kink-bands would be "inclined at  $60^\circ$  to the direction of compression as opposed to  $45^\circ$  in Taylor's problem".

My own suggestion<sup>2</sup> is as follows. In an ideal foliated body, kink-bands, like shear planes (in that they constitute a zone of yielding and in that they effect a displacement), would also propagate at an angle of  $45^\circ$  to the direction of compression, as the same theoretical argument<sup>8</sup> seems relevant to both structures. In kink-bands the geometry of shearing is such, however, that frictional effects will tend to increase rather than decrease the  $45^\circ$  angle with  $P_{\max}$ . This is because shearing takes place not on the kink-plane but on the intra-kink-band foliation. The orientation of the latter changes during shearing, but its mean position is approximately perpendicular to the band<sup>2</sup>. Hence the necessary approximation and the positive sign in my statement, "kink-bands might be expected to make an angle of about  $90 + \phi/2$  degrees with the same major principal stress"<sup>2</sup>, which I applied only to the case of the symmetrical conjugate set. Both hypotheses are in accord with the experimental results so

far obtained. Further experiments to check their validity thoroughly would not be difficult.

Incidentally, Marshall<sup>1</sup>, in attempting to summarize my ideas for criticism, has distorted the original and has attributed to me views which I have not expressed and do not hold. To take a single point, his observations on the final position of the rotating internal shear planes do not invalidate, but in fact support strongly, my contention that the mean orientation of these planes during shearing is at about  $90 - \phi/2$  degrees with the maximum principal pressure<sup>2</sup>.

### Volcanoclastic Rocks in Tenerife, Canary Islands

IGNIMBRITES are commonly of rhyolite, rhyodacite or dacite composition, less commonly of andesite composition, and rarely of basalt composition. Ignimbrites associated with sodic-alkaline volcanism are rare and known examples are restricted to the Kenya field, although doubt has been cast<sup>1-3</sup> on their ignimbrite origin<sup>4</sup>, and it has been suggested that they are more akin to froth flows. A preliminary examination of a series of rocks from Tenerife indicates that in this, another sodic-alkaline environment, a number of different types of volcanoclastic flow may be distinguished.

The volcanic rocks of the Canary Island Archipelago are dominantly alkaline, and in the area of the Las Canadas caldera, Tenerife undersaturated basalts and phonolites form a capping to the basement alkali-olivine basalts and ankaramites. Within the walls of the caldera, and on the outer flanks, are exposed a series of volcanoclastic rocks which are divided in the field into ignimbrites, pumice flows and eutaxites.

The ignimbrites are nowhere more than 12 ft. thick, yet in vertical section they display zonal characteristics commonly associated with much thicker flows. Generally four major zones can be distinguished: (1) a basal incoherent or weakly coherent zone; (2) a zone of maximum welding with abundant fiamme; (3) an indurated zone caused by post-depositional recrystallization; and (4) a surface incoherent zone.

Locally, within one of the ignimbrites, a second fiamme zone may separate zones 3 and 4, which suggests that the unit is not a simple cooling unit, and a marked increase in crystal content above zone 2 further suggests that some crystal settling had occurred in the chamber from which the flows were emitted, so that the initial "pulses" tapped the top part of the chamber which was depleted of crystals. The zones rich in crystals contain mainly intratelluric anorthoclase, with rare brown biotite, aegirine-augite, brown amphibole and sphene.

The secondary recrystallization begins just above the zone of maximum welding and is represented by axiolitic and spherulitic growths of alkali-feldspar within the pumice fragments, and a clouding of the glassy groundmass. The disrupted nature of the matrix is clearly evident, tricuspidate shards and elongate pumice fragments being seen in various stages of welding and compaction.

Pumice flows have been located only on the outer flanks of the volcano, where a number of flows from a series 20-30

ft. thick. Distinct changes are seen in vertical section, from the basal to the topmost flows, which are due to variations in the amount of pumice in individual flows. The basal flow is a mixture of flowing greenish-grey pumice and partially vesiculated black obsidian. The flow above this is completely pumiceous, with a base of incoherent grey pumice, a thin zone of maximum welding containing distorted and flattened pumice fragments, and a thicker upper zone of welded but undistorted pumice lumps. Above this the flows show a rapid increase in lava content which culminates in the topmost flow which contains only a small amount of pumice and is almost a true phonolite lava.

Together these pumice flows may represent a complete cycle of activity; the basal flows indicate the first stages of vesiculation, the flow above this represents the major phase of vesiculation and the topmost flows the waning stages when the gas had almost been depleted and only true lava was being emitted.

A third type of volcanoclastic flow is represented by the eutaxites. These were originally described from Tenerife<sup>5</sup>, when the term eutaxite was used to describe "a banded or flamed appearance" imparted to the rocks by alternations of either glassy and cryptocrystalline layers or cryptocrystalline and microcrystalline layers. The term has gained favour in ignimbrite nomenclature and is used to describe the flowing appearance given to a rock by the intermingling of pumice shreds and disrupted groundmass. Often if the pumice is completely flattened the "eutaxitic" texture is even more noticeable.

According to Ross and Smith the eutaxites of Tenerife "seem almost certainly to have been welded tuffs or at least welded clastic rocks"<sup>6</sup>. Re-examination of these rocks shows that although they may have the megascopic textural features of ignimbrites, that is a distinct flowing nature caused by irregular alternations of streaks of different colour, microscopically they show no criteria by which their ignimbrite origin may be proved.

In these rocks from Tenerife the eutaxitic texture appears to be formed by the alternation of areas of primary microcrystallization and glass, the crystalline areas being composed of unoriented alkali feldspar laths and shreds of aegirine. To what extent such textural relationships can be allied to McCall's hypothesis for the Kenyan eutaxites is not yet known, but the statement of Fritsch and Reiss<sup>7</sup>, that "in the Canadas Mts. these peculiar rock types occur in the superficial parts of lava streams, the main mass of which are phonolitic homogeneous rocks", suggests that there may be similarities between the eutaxites of Tenerife and the rocks described from Kenya.

Several preliminary conclusions may, therefore, be drawn from the types of flow the features of which are briefly outlined above. (1) Ignimbrites which display features commonly assumed to be the result of deposition from an emulsion of gas and solid can occur in an environment of sodic-alkaline volcanism. (2) The ignimbrites have an average thickness of only 12 ft. and so a large overload pressure is precluded. If temperature and overload pressure are the two dominant factors which produce the zonal arrangements commonly seen in ignimbrites, then for the rocks from Tenerife the temperature of emplacement must have been high, so that the shards and pumice fragments were plastic enough to deform under a small overload pressure. (3) The series of pumice flows may represent a "cycle of vesiculation". The crude zonal arrangement seen within the completely pumiceous unit suggests that it may have been deposited in a similar way to an ignimbrite, although it was different in that vesiculation was not followed by complete disruption of the magma. (4) The eutaxites of Tenerife are probably not true ignimbrites, and they are certainly not similar to the ignimbrites described as such here. Further investigation may indicate that they have close affinities with the eutaxites of McCall<sup>8</sup>, because the crystalline areas appear to be of primary origin and are not similar to the

areas of secondary recrystallization within pumice fragments, which are a common feature of many true ignimbrites.

### Shock Metamorphism in the Carswell Circular Structure, Saskatchewan, Canada

PETROGRAPHICAL features such as multiple sets of deformation lamellae in quartz, isotropic quartz and feldspar, and characteristic microfracture patterns, are generally believed to be diagnostic of hyper-velocity impact<sup>1</sup>. These features can be produced experimentally by shock pressures of tens or hundreds of kilobars, which, it is assumed, can only be generated in nature by the hyper-velocity impact of large missiles. All these features occur in the Carswell circular structure, however, in circumstances which cast doubt on this theory.

The Carswell structure (Fig. 1), centred near 58° 24' N., 109° 30' W., occurs in the flat-lying Athabaska sandstone of Proterozoic age. The Carswell dolomite is known as a "toroidal" inlier downfaulted several thousand feet into the Athabaska formation. An exposure of pre-Athabaska

Fig. 1. Geological sketch of the Carswell circular structure.

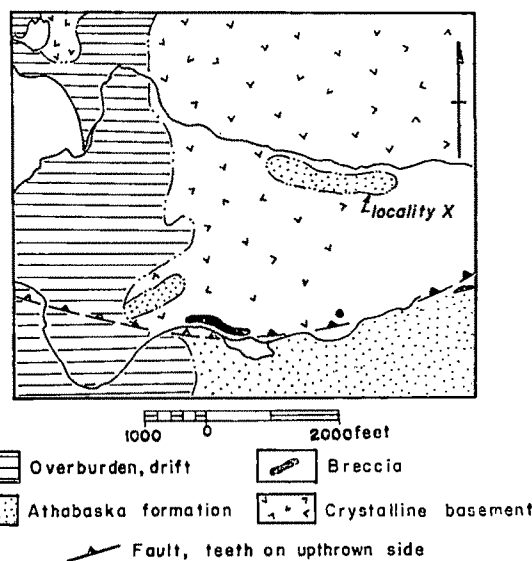

Fig. 2. Detailed geological sketch of small area of the Carswell structure.

crystalline basement, roughly circular and about 12 miles in diameter, occupies the centre of the structure. This outlier is the only one known in the 13,000 square miles covered by the Athabaska formation. Movement some hundreds of feet along a fault has juxtaposed basement rocks against the upper part of the Athabaska formation. Numerous small outliers of the lowest beds of the Athabaska formation red pebble conglomerates and sandstones are scattered over the pre-Athabaska surface.

At point X in Fig. 1, an outlier of Athabaska sandstone lies on the basement, and at the contact there is an unconformity which is well exposed. A detailed geological sketch of the area is shown in Fig. 2; Fig. 3 is a photomicrograph of quartz-garnet rock from the basement. This shows multiple sets of numerous deformation lamellae in the quartz grains. Initiation of fractures is seen in the lower right part of the field, and in the upper left corner the lamellae disappear into an area of amorphous material. According to the criteria of Short<sup>2</sup>, this rock has undergone moderate to strong shock metamorphism. Examples of such shock metamorphism are found sporadically over all the basement rocks.

Fig. 4 is a photomicrograph of Athabaska sandstone from immediately above the contact. There is no unusual

Fig. 3. Biotite-garnet-quartz gneiss, from lower side of contact at locality X, Fig. 1. Plane polarized light,  $\times c. 25$ .

deformation of the well cemented pebble sandstone, and the rare cracks which can be seen are typical of grains of the Athabaska formation.

Two thousand five hundred feet south of this area, breccia occurs in a fault zone which separates the basement from the upper part of the Athabaska formation (Fig. 2). The breccia contains fragments of shocked basement and unshocked Athabaska formation, and typical shock metamorphic features such as veinlets of heterogeneous glass, and biotite showing kink-bands. The Athabaska formation on the south side of the fault is undeformed, although before faulting it was several hundred feet nearer to the centre of the structure than the moderately shocked north wall. Shock deformation has not been detected in the Athabaska formation.

If the Carswell structure is an eroded impact scar, as suggested by Innes<sup>3</sup>, either maximum pressures were low in the Athabaska formation and increased abruptly in the underlying basement, or impact took place before the Athabaska sandstone formed and the glass-bearing breccias developed after formation. The latter alternative separates the supposed "impact metamorphic" phenomena into two categories occurring at widely different times, while the former appears to violate the laws of shock wave propagation. The shock impedance of the sandstone and basement is virtually identical below a few hundred kilobars (specific gravity of the sandstone 2.49, specific gravity of basement 2.48–2.52), so that the peak pressure of a shock propagating downwards must diminish as some power of the distance from the centre.

Fig. 4. Pebble sandstone with graded bedding, from upper side of contact at locality X, Fig. 1. Well rounded, unfractured larger grains of quartz and the partly sutured finer material are both typical of the Athabaska formation. Black areas are haematite cement. Plane polarized light,  $\times c. 13$ .

The phenomena can be explained by assuming that a strong shock wave propagated upwards through the basement, and was reflected, or considerably reduced, at the interface with the Athabaska formation—a model which attributes shock metamorphic effects to terrestrial processes. Alternatively it might be concluded that identical criteria are perhaps produced by causes other than shock pressure.

## PHYSICS

### Symmetry of the Time Axis and Solar Observations

I SHOULD like to offer two comments on Stannard's<sup>1</sup> recent interesting postulate that there exists a counter-world to compensate for the asymmetries of nature that we find in our own world. The first comment proposes that observations do not exist to support his postulate, but that the counter-world suggested by the observations is of a somewhat different character. The second is a reconciliation between the two possible counter-worlds; Stannard proposes to add the faustian world to the present laws of physics to eliminate the asymmetries, whereas the observations suggest that the present asymmetries of physics have arisen because the present physical laws reflect an observation of the faustian world. In particular, our present physical laws could be said to be based on the assumption that the faustian universe is a contracting universe.

It is first necessary to outline the alternate counter-world suggested by the observations. Although this picture differs from Stannard's, I shall borrow the name "faustian". Our world is the real world and the counter-world is the "faustian" world. These worlds are relative in the sense that to the extent that real man can construct the faustian world mathematically, it is indistinguishable from the real world, but in so far as man can observe the faustian world, it is a real world that moves backwards in time. I do not wish, however, to say that the faustian world is moving backwards in time; such a statement has no meaning. Rather the real and faustian worlds are separate spaces and are related to one another as the Hermetian quaternion ( $ix, iy, iz, ct$ ) is related<sup>2</sup> to the metric quaternion ( $x, y, z, -ict$ ). Nevertheless in both worlds there is an absolute direction in time: a universe that expands and in which matter diffuses is said to move orthotropically; a universe that contracts and in which gases unmix is said to move paratropically. Both directions are absolute in either world, and indeed it is because of the preferred direction in time that the counter-world must be postulated.

The alternative picture to Stannard is very simple. I assume that real spontaneous emissions are "caused" by the absorption of faustian photons and that absorption of real photons "causes" the emission of faustian protons. I further assume that for every emission of a real photon from real matter, there is a corresponding absorption of a faustian photon into faustian matter. Between the two worlds there is no energy exchange—energies which are called real are transferred between real atoms by real photons; energies which are called faustian are transferred between faustian atoms by faustian photons. Although there is no energy exchange, there is nevertheless an exchange of causality. I now indicate how this causality exchange would be seen in observations of real atoms, not in thermal equilibrium.

In calculating the relative ratio of emission to absorption  $\epsilon/a$  for a particular bound-bound level transition, it is customary to write

$$\epsilon/a = N_e/N_a \neq e^{-h\nu/kT} \quad (1)$$

where  $N_e/N_a$  is the relative population ratio of the emitting atoms to absorbing atoms the energy difference of which is  $h\nu$ . For equilibrium (Planckian) radiation, or for a high rate of collisional excitation and de-excitation, the population ratio is given by  $e^{-h\nu/kT}$ . If, however, we replace the usual photon vacuum state of emission and absorption—the state to which and from which real photons are created and annihilated—by the faustian photon state, it is easy to show that the ratio

$$\epsilon/a = e^{-a} N_e/N_a \neq e^{-a} e^{-h\nu/kT} \quad (2)$$

in general where

$$e^{\alpha} = \frac{1 + \hat{N}}{\hat{N}} \quad (3)$$

is the ratio of final and initial state factors, that is, treating faustian photons as bosons. We additionally note that as  $\hat{N} \rightarrow \infty$ , the usual rules of physics are operative, and in effect, the faustian photon state may be replaced by the vacuum state. On the other hand, if  $\hat{N} \rightarrow 0$ , the ratio goes to zero, that is, spontaneous emissions cease.

The first evidence of a diminution of spontaneous emission in a non-equilibrium situation is indirect. If one applies the conventional equations and formulae of statistical mechanics in the non-equilibrium situation of the Fraunhofer line forming region of stars—low matter density and strong non-equilibrium radiation field—one can calculate large radiative imbalances which in turn cause large departures of  $N_e/N_a$  from the Boltzmann equilibrium ratios  $e^{-h\nu/kT}$ . Such departures are not observed—except in the sense that a systematic march of increasing temperature into the star is claimed to be derived if the Boltzmann distributions are assumed. The argument as to whether the atom populations are those given by the assumed Boltzmann distributions or those given by the theoretical calculations is a subject of much lively debate—the celebrated L.T.E. *versus* non-L.T.E. dilemma of modern solar physics<sup>3-5</sup>. The complete controversy, however, could be eliminated (an agreement between theory and observation could be said to exist) if the effect of the depletion of faustian photons could be incorporated into the non-equilibrium theory: spontaneous emissions (depending on the faustian photon density) would accordingly be theoretically reduced, and the presently predicted radiative imbalances diminished.

The second evidence is more direct. In the deeper and denser regions of the Sun—the photosphere—where the continuum radiation originates, the atom populations which effect the continuous radiation can be assumed to be given by their Boltzmann distributions because of the high rate of collisions. (The radiation field remains as before, non-Planckian.) And on this account Kirchhoff's law is traditionally used in the analysis of the solar photosphere, that is,

$$S_{\nu} = 2h\nu^3/c^2(e^{h\nu/kT} - 1)^{-1} \quad (4)$$

Our new picture demands that Kirchhoff's law be replaced by a source function conjectured by Wildt<sup>6</sup> of the Kothari-Singh<sup>7</sup> form

$$S_{\nu} = 2h\nu^3/c^2(e^{\alpha}e^{h\nu/kT} - 1)^{-1} \quad (5)$$

where the quantity  $\alpha$  is defined in equation (3). This source function can be distinguished from the Kirchhoff source function through a comparison of the empirical solar opacity to the theoretical solar opacity. The comparison is in the nature of the removal of a discrepancy of 300 per cent in the relative ratios of empirical to theoretical opacity over the wavelength range  $\lambda\lambda 5,000-24,000$  (ref. 7).

*The contracting universe.* In contradistinction to Stannard's suggestion, the present picture suggests that it is the absence of faustian matter that will decrease the emission of a thermal detector (or atom). Thus, the problem of the present or new picture of the counterworld is to explain why spontaneous emission is the natural state of affairs. That is to say, why are the traditional rules of physics approached as  $\hat{N} \rightarrow \infty$  and not as  $\hat{N} \rightarrow 0$ ? We examine this question by a reconsideration of Obler's paradox.

Obler's paradox simply asks: Why is the night sky not as bright as the average star (or the Sun)? And the paradox is only adequately answered by concluding that the universe must be expanding. Our paradox, however, is the reverse. Why, in traditional physics, that is,  $\hat{N} \rightarrow \infty$ , is the faustian night sky radiation so bright? And in the same logic of Obler's paradox, we must conclude that the faustian universe as seen by an orthotropically moving observer, is seen as a paratropically moving universe,

that is, it is a contracting universe. Thus, stars, instead of being brighter than the background night sky radiation, are instead merely occasional cool regions (or faustian photon sinks) superposed over an extended hot bright faustian sky. Indeed, it is on account of this intense faustian radiation that—for many conditions—Dirac's historic assumption that negative energy states are all occupied is possible.

Thus Stannard's picture of faustian stars being "cool" against the "night sky" radiation is correct, but the present picture would suggest that the "night sky" observation is in our physical laws rather than as a direct observation. With respect to direct observation, however, the surfaces of stars are cool in the sense that there are insufficient faustian photons to cause spontaneous emission. That is to say, stars produce orders of magnitude more real photons than they absorb—perforce in compensation they emit far less faustian photons than they annihilate. And therefore it is in the observation of the breakdown of the traditional physical laws on the surface of stars that is the primary observation.

Finally, instead of ending in a note of speculation, I should like strongly to urge that the counter-world, defined as the space orthogonal to ours, be designated as the faustian counter-world. There may exist other places in the mathematics where other counter-worlds can be postulated, but the orthogonal counter-world makes some sense in being called faustian. Further, this counter-world seems to hold the most theoretical promise as a working tool; there is no difficulty, for example, in giving a mathematical explanation as to why the real world has an electric current but no magnetic current.

## Technique for Detecting Lead Particles in Air

TECHNIQUES for counting airborne lead particles would be useful in studies of air pollution. No available technique detects lead particles less than  $5\mu$  in diameter, and particles larger than this reside in the atmosphere so briefly that they are probably not a hazard to health. The present methods for measuring lead in the air<sup>1</sup> give only the mass of lead per unit volume. The effect on human beings of a particulate suspension cannot be assessed from mass alone, as capture in the lungs depends on particle size<sup>2</sup>.

This communication describes preliminary trials of a new method of detecting lead particles, based on the activity of lead iodide as an ice nucleating agent<sup>3</sup>.

We detect ice nuclei with an acoustical counter<sup>4</sup>. This instrument, developed at the National Center for Atmospheric Research (NCAR), Boulder, Colorado, counts the active ice nuclei in the air on a continuous real time basis at any desired temperature. In our experiments, air entering the counter is first passed through a small mixing chamber containing iodine crystals. Lead particles are thus converted into lead iodide which is active as an ice nucleus at sizes probably extending down to  $0.01\mu$  diameter, depending on the temperature. The lower the temperature of the cold chamber, the smaller the active particles.

Laboratory trials have established that lead particles (generated by heating lead beyond its melting point) do indeed form lead iodide in the mixing chamber, and that

these do cause ice crystals to form in the cold chamber of the counter. Lead particles without iodine do not act as ice nuclei, and iodine alone, in air free from particles, has no activity as an ice nucleus, at least at temperatures above  $-15^{\circ}\text{C}$ . Burning unleaded gasoline (white gas) produces no ice nuclei with iodine, while the exhaust from an automobile burning leaded fuel produces many nuclei.

In trials outside the laboratory with the counter at a temperature of  $-15^{\circ}\text{C}$ , the iodine-ice nucleus count is low or zero in the clean air which blows from the mountains west of Boulder, but when the wind becomes easterly and blows across the city, the count becomes very high, sometimes exceeding the capacity of the counter (the maximum counting rate is 10,000 particles/min, corresponding to 1,000 particles/l.).

Fig. 1 shows the records obtained on two consecutive days near a busy intersection in the centre of Boulder. The instrument was mounted in an automobile parked about 25 yards south-east of the intersection. On October 25 the wind was light and generally easterly, so that the instruments were upwind of the intersection. There were intermittent periods of calm. The air temperature was warm enough to create considerable vertical transport by convection, and the surface air could be expected to become diluted with cleaner air from higher levels. The counts at  $-14^{\circ}\text{C}$  were quite low at midday but rose through several orders of magnitude as the afternoon progressed. The increase was probably due to a slackening in the rate of vertical mixing as the temperature fell from 1400 h on. Traffic was moderate throughout the afternoon until the evening rush started, just before 1700 h. Shortly after 1700 h the count rate went off the scale and remained off. To get back on to the scale the counter was set at a warmer temperature ( $-12^{\circ}\text{C}$ ). Next morning the early rush, combined with the stable inversion conditions characteristic of that time of day and a dead calm, produced a very high rate of count. At  $-14^{\circ}\text{C}$  the count rate was off scale and at  $-12^{\circ}\text{C}$  it was near the top of the scale. This day was also warm and, as the temperature rose rapidly, the count decreased greatly. By 1130 h it had dipped below 1 particle/l., so the counter was cooled down to  $-14^{\circ}\text{C}$ . The count at this temperature was just coming back on scale, and occasionally going off scale. These results suggest that this technique may be useful in monitoring air pollution. It remains to be shown, however, that what is being counted is indeed lead. Other substances can also react with iodine to form ice nuclei. Silver would do so, but is unlikely to be present in suffi-

ent concentrations in outside air. Terpenes also form ice nuclei with iodine<sup>6</sup> and are likely to be present.

Some of this work was carried out with the collaboration of Dr. Ottavio Vittori, director of the Osservatorio di Monte Cimone, Italy, while he was visiting the United States. His assistance and encouragement are acknowledged. The co-operation of J. Rosinski, G. Langer and A. D. Gibson of NCAR was essential to the entire study.

### Aspects of Similarity for Air-entraining Water Flows

Air is often entrained naturally by flowing water—for example, in the plunging waters of mountain streams, waterfalls, bores, breakers, hydraulic jumps and subterranean siphons—and, in these and similar situations, appears generally to be beneficial. The quality of the water, certainly, is improved by air entrainment and very few hazards tend to arise with these naturally occurring flows.

Air entrainment is, however, also encountered in many artificially contrived situations and its various influences must then be carefully studied. Engineering projects in which air entrainment exerts a significant influence include open channels with fast-moving water flows, which require depths adequate to accommodate air entrainment<sup>1</sup>; "morning-glory", air-entraining, spillways which individually must have the capacity to discharge the estimated flood and its entrained air<sup>2</sup>; spillway discharge tunnels which require adequate ventilation (to suppress tendencies to surge); siphon spillways, especially those which are deliberately air controlled (to allow the close regulation of the levels of lakes or rivers<sup>3</sup>); flood control gates, or weir structures (which need substantial and adequate ventilation<sup>4</sup>); vortex-tube drop shafts<sup>5,6</sup>; air lift pumps; and air exhausting, water jet pumps.

Regardless of whether air entrainment must be induced or discouraged, adequate knowledge of the flow pattern is essential for proper engineering design. Unfortunately, it seems that water flows which entrain air are still not yet amenable to satisfactory theoretical treatment and, in consequence, resort has been widely made to the use of hydraulic models. Even with these, however, the problems of correct scaling have still not been satisfactorily resolved. It is well known that air entrainment studies on simple Froude models, tested in the Earth's atmosphere, are subject to significant error<sup>2,4,7</sup>. Escande has demonstrated that such models necessarily entrain insufficient air<sup>8</sup> and it has been suggested that this type of test should be conducted in suitably scaled "model atmospheres". Tests recently undertaken at the Imperial College of Science and Technology on a full-size siphon under atmospheric conditions and on a one-sixth linear scale model air controlled siphon, initially under atmospheric conditions and finally in a one-sixth scale model atmosphere, indicate that significant inherent scale effects still persist, perhaps because of the incorrectly scaled, yet influential, surface tension forces and viscous forces.

Studies of the formation of vortices and swirls at intakes<sup>9</sup> and, more recently, studies with air-controlled siphons<sup>10</sup>, have indicated that the use of full scale velocities and pressures might provide useful similarity

Fig. 1. Ice nucleus concentration in iodine-treated air (Boulder, Colorado, October 25-26, 1966); — — — indicates instrument off data collected at  $-14^{\circ}\text{C}$  unless noted.

criteria for studies of air entraining water flow and, in fact, it now seems that there may be some theoretical foundation for such notions. In considering incipient air entrainment in vortices, it has recently been emphasized<sup>11</sup> that when prototype and model fluids are identical the use of full scale velocities as a criterion of similarity is tantamount to ignoring the influence of inertia forces. Thus, when viscous and surface tension forces are together considered to dominate the pattern of flow and are identically scaled, the following ratios will necessarily be identical (in corresponding prototype and model situations)

$$\frac{\text{Viscous forces}}{\text{Surface tension forces}}; \text{ or } \frac{\left(\mu \frac{dv}{dy}\right)(\text{area})}{\sigma l};$$

or, alternatively,

$$\frac{\text{Weber numbers } \left(\frac{\rho v^2 l}{\sigma}\right)}{\text{Reynolds numbers } \left(\frac{\rho v l}{\mu}\right)}$$

will be the same in model and prototype. Thus for dynamic similarity between the viscous forces and the surface tension forces

$$\left(\frac{\mu v}{\sigma}\right)_{\text{model}} = \left(\frac{\mu v}{\sigma}\right)_{\text{prototype}}$$

or, when the same fluids (for example, air and water) are in use

$$v_{\text{model}} = v_{\text{prototype}}$$

(where  $\mu$  is the coefficient of absolute viscosity and  $\sigma$  is the coefficient of surface tension).

Precedent for the deliberate neglect of the influence of inertia forces, in order to achieve identical scaling of other pairs of significant forces, has been previously created in the resolution of various other flow systems—for example, those in which viscous and gravitational forces are considered to be dominant and where similarity can be attempted by equating ratios of

$$\frac{\text{Gravitational forces}}{\text{Viscous forces}} \text{ or, in effect, of}$$

$$\frac{\text{Reynolds numbers } \left(\frac{\rho v l}{\mu}\right)}{\text{Froude numbers } \left(\frac{v^2}{gl}\right)}$$

Such situations arise, for example, during hydraulic model studies of geological (or tectonic) movements<sup>12</sup>; in studies of hydraulic models of flow patterns in glass furnaces<sup>13</sup>; and, generally, in studies of free surface laminar flows under the influence of gravity<sup>14</sup>.

The influence of inertia forces has also been deliberately neglected, and the ratio  $(\mu v/\sigma)$  introduced, when contemplating various other situations in which viscous and surface tension forces are dominant, for example, when considering the distortion of drops in a shear flow during the formation of emulsions<sup>15</sup>; when considering the sintering and rounding of sharp edges by heat in glass technology<sup>16</sup>; when defining the boundary conditions of cavities in thin (lubricating) films<sup>17</sup>; when describing the surface waviness in annular two phase pipe flow<sup>18</sup>; and when contemplating the atomization of liquid fuels<sup>19</sup>.

The ratio  $(\mu v/\sigma)$  has not, however, to our knowledge, previously been applied to the study of air entraining water flows. Nevertheless, air entraining water flows necessarily carry air bubbles and in some cases the air bubbles can be introduced into the main flow with drops of water. Neither air bubble size nor water drop size is sensitive to linear scale and yet each is very much dependent on surface tension forces and doubtless also on viscous forces. Significantly, the ratio  $(\mu v/\sigma)$  (that is, viscous force/surface tension force) is independent of

linear scale and it seems likely that this ratio may be usefully adopted as a criterion of similarity for studies of air entraining water flows. Support for this suggestion stems from the studies on the formation of vortices and swirls<sup>9</sup> and on the air regulation of siphonic flows<sup>10</sup>.

## Transport Processes and Thermodynamic Equilibrium

THERE is an error in my article in *Nature* under the above title<sup>1</sup>. The error occurs at the point where the chemical potential  $\mu$  is introduced as an undetermined multiplier and is in equation (7), the restriction on the volumes of the various parts of the system in a virtual reversible infinitesimal displacement of the system at constant total volume, mass, and entropy. The restriction given, that is,

$$\sum_i (\delta V_i + v_i \delta M_i) = 0$$

is appropriate when there are no long range gravitational or electrostatic potential forces, whereas for the increment in the total energy arising from such forces to be  $\sum_i \phi_i \delta M_i$ ,

a much stronger restriction must be applied, namely, for every region  $i$ ,

$$\delta V_i + v_i \delta M_i = 0$$

The erroneous restriction would lead to the conclusion that there is a uniform pressure throughout the system, which is true only if there are no long range forces. Using the correct restrictions to eliminate  $\delta V_i$  from the expression  $-p_i \delta V_i$  for the work done on the  $i$ th part of the system, it is then necessary to introduce only two undetermined multipliers  $T$  and  $\mu$  to deal with the restrictions on total mass and entropy. This results in the two conditions of equilibrium, namely, uniform temperature and a constant value, through the system, of

$$\mu = u_i - T s_i + p_i v_i + \phi_i$$

• Using this equation and following the method of ref. 1 it is easy to show that in a virtual displacement involving a deformation as well as a change of mass of the whole system

$$\bullet \quad dU = T dS + dW + \mu dN$$

where

$dW = -\sum p_i dV_i$  is the total mechanical work

performed on the system, and  $dV_i$  is the increment in volume of part  $i$  arising from both the deformation and the change of mass, and  $\mu$  is independent of the point in the system at which  $dN$  has been introduced.

The remainder of the article is not affected by this error.

## THE SOLID STATE

### Early Fading of Thermoluminescence Induced by Radiation in Lithium Fluoride

IN a previous report<sup>1</sup> the fading of thermoluminescence induced by ionizing radiation in lithium fluoride has been discussed, but little attention has been paid to fading that may occur during the first 24 h after irradiation. Knowledge of, or elimination of, early fading will be of interest when it is desired to read out, with a precision of a few per cent, a group of samples soon after irradiation. Some users of lithium fluoride wait 24 h until the rate of fading has decreased enough so that fading will be negligible during the measurement of all the samples. Under certain circumstances, however, this delay is inconvenient.

Curve A of Fig. 1 indicates a typical curve of fading for 'Con-Rad Type 7' powder from a batch which had been exposed to a "standard" annealing of 1 h at 400° C plus 24 h at 80° C before use. The earliest measurement was taken 1 min after 3.5 min of exposure. It is clear that if the readout of a sizable series of samples irradiated simultaneously as a group is begun soon after irradiation, the fading can be more than a few per cent by the time the final sample is read out. It is also clear that the rate of fading decreases with time, so that one could decide, on the basis of such a fading curve, to delay readout until the amount of fading over the time span for reading all the samples is tolerable. We have found the effect to be quantitatively about the same over a range of exposures

Fig. 1. Fading curves. The earliest readouts are at 3 min after exposure and are normalized to 100 per cent. Curve A, normal readout cycle; curve B, with readout cycle altered so that the photomultiplier does not function during the first 4.5 sec of the heating cycle.

Fig. 2. Glow curves showing the decrease of the low temperature peak as the time between irradiation and readout is varied. From left to right, the delay between exposure and readout is 1 min, 8 min, 30 min, and 1.5 h. ('TLD 100', cobalt-60.) The time scale runs from left to right. The corresponding readouts were 548, 527, 518, 514. Curves were made using a 'Fluke 840A' electronic galvanometer and an oscilloscope with camera. (The electronic galvanometer requires almost 1 sec to reach 90 per cent of full response.)

from 10 r. to 1,000 r. of X-rays and  $\gamma$ -rays, independent of radiation quality and independent of exposure rate up to 250 r./min, the highest rate we studied. The two types of powder ('TLD 100' and 'Con-Rad Type 7') behaved in essentially the same manner. It is obvious that in instances of long exposure, early fading will be difficult to observe.

By recording glow curves we have shown that early fading is caused principally by decay of the low temperature peaks described by Zimmerman and associates<sup>2</sup>. Fig. 2 is a series of glow curves with the zero times displaced for the sake of clarity. The curves were made 1 min, 8 min, 30 min and 1.5 h after exposure, and the low temperature peak is seen to decrease progressively with time. (We use a 'Con-Rad TLD' reader and either lithium fluoride 'Con-Rad Type 7' or 'TLD 100' powder for radiation dosimetry.)

Zimmerman and associates<sup>2</sup> have also shown that the low temperature peaks are not present if the powder is annealed after irradiation for 10 min at 100° C, but early fading was not discussed specifically in relation to the low temperature peaks.

Curve A of Fig. 3 is a fading record for powder not annealed after irradiation. Each point on these curves represents an average of three readings. Curve B is for powder irradiated identically but annealed in the capsules for 10 min in the top of a double boiler at 100° C. The absolute readings were 10 per cent less than the highest readings of the unannealed powder, but the fading was not more than 1 per cent over the 8 h period studied. While this post-annealing removes the early fading, it does introduce some inconvenience.

Another method we have used to avoid early fading is to programme the readout cycle so that the phototube current circuit is held open by a time-delay relay until the low temperature peaks have been passed. The delay needed depends on such factors as heating current, initial temperature of planchet, and so forth. Fig. 1 shows fading records for powder readout with a normal cycle (curve A) and for powder readout with a 4.5 sec delay (curve B). Fading of the readout has been reduced to approximately 1 per cent. The absolute readings which used the delay were 8 per cent less than the highest readings which used the normal readout cycle. This percentage will vary with the amount of delay and the length of time that has elapsed between exposure of powder and readout. This arrangement permits minimal inconvenience and elapse of time between the end of irradiation and readout, but if the heating rate of the powder is changed, there will be

Fig. 3. Fading curves. The earliest readouts are normalized to 100 per cent. Both curves begin 12 min after exposure. Curve A, normal readout; curve B, with 10 min post irradiation annealing at 100° C. Each point is an average of three values.

a change in the fraction of the glow curve that is programmed out and, thus, a change in reader calibration. (Details of the modification of our reader will be sent on request.)

Two other methods for elimination of effects of early fading might be (1) to incorporate a short annealing at 100° C as the first part of the readout cycle, and (2) to correct the readings on the basis of a fading curve for the same batch of lithium fluoride powder.

### Etching of Dislocations in Crystals of Aromatic Hydrocarbons

STUDIES of the defect structure of single crystals of aromatic hydrocarbons have revealed that "as grown" crystals contain a high concentration of dislocations<sup>1,2</sup>. These defects have a marked effect on the physical properties of the solid<sup>3,4</sup>. It is therefore desirable to have some method of determining dislocation concentrations in these solids so that the magnitude of this effect can be assessed. Previous attempts to study the dislocation structure of aromatic hydrocarbon solids by thermal etching<sup>5</sup>, electrolyte etching<sup>6</sup>, and enzyme etching<sup>7</sup> have produced oriented but ill-defined etch patterns. This communication reports the results of some attempts to etch such crystals using solvent and chemical etches.

A variety of possible chemical etchants were tried on very pure single crystals of anthracene and naphthalene grown from the melt by the Bridgman technique. Bromination, nitration and oxidation produced ill-defined patterns. Sulphonation with fuming sulphuric acid (65 per cent sulphur trioxide) diluted 1 : 10 with concentrated sulphuric acid proved most suitable. Freshly cleaved crystals were dipped in the acid, rapidly washed with water and dried. The vigorous reaction yielded a dark

brown reaction product which dissolved in the water to leave a clean etched surface. With anthracene the reaction was instantaneous; longer immersion periods (10 sec) were required for naphthalene. Well-defined rhombic etch pits were produced on the (001), *ab*, surfaces of anthracene crystals (Fig. 1). Attempts to etch other crystal faces were unsuccessful. When the etched crystals were examined between crossed 'Polaroids' with the beam normal to the (001) surface the isogyre was observed to be parallel to the long axis of the pits. For anthracene and naphthalene (monoclinic crystals) the optic plane is (010) and the *b* axis,  $\langle 010 \rangle$ , is a principal axis<sup>8</sup>. The isogyre will therefore be parallel to the  $\langle 100 \rangle$ , *a*, direction. Hence the long and short axes of the etch pits are aligned parallel to the *a* and *b* axes respectively. Close examination of the pits under high magnification showed that the pits may be inclined along the  $\langle 001 \rangle$  direction. Thus it is possible that the pits lie at the emergent ends of dislocations lying parallel to the  $\langle 001 \rangle$  direction. The possibility that dislocations of this orientation exist in naphthalene has been suggested by Gordon<sup>8</sup>. An excellent mirror image relationship was found between etch patterns produced on adjacent cleaved surfaces (Fig. 1).

Etch pits produced on naphthalene (001) surfaces using the same technique were initially similar in shape and orientation to those observed with anthracene. Because of the high volatility of the solid the pits rapidly developed into polygonal pits or lost their shape completely. Etching, followed by rapid photography, enabled reasonably well-defined patterns to be obtained. At a later stage the pits merged together and were not distinguishable. Fig. 2 shows an etched naphthalene surface at an intermediate stage.

Solvent etches, either water or mixtures of organic solvents with water, gave etch patterns similar to that shown in Fig. 3. The pits were conical in shape and showed no particular orientation with respect to the crystal axes. With naphthalene these etch pits were more stable than those produced by the acid etch; however, with time these pits again developed and became diffuse.

Table 1		
Crystal	Treatment	Dislocation content (cm <sup>-2</sup> )
Anthracene	As grown	10 <sup>8</sup> -10 <sup>7</sup>
	Annealed 200°, 100 h	10 <sup>8</sup> -10 <sup>6</sup>
	Anthraquinone doped, annealed as above	10 <sup>8</sup>
Naphthalene	As grown	10 <sup>8</sup> -10 <sup>6</sup>
	Annealed 78°, 280 h	10 <sup>8</sup> -10 <sup>4</sup>

Dislocation counts were made on etched crystals which had been subjected to various treatments. The details are given in Table 1.

As grown crystals of anthracene and naphthalene contain a high concentration of dislocations. This no doubt results from the strain induced during growth in a closed vessel. Lengthy annealing periods at temperatures close

Fig. 1. Adjacent cleaved (001) faces of an anthracene crystal, sulphuric acid etch ( $\times c. 135$ ).

Fig. 2. Naphthalene crystal (001) face approximately 30 sec after sulphuric acid etching ( $\times c. 135$ ).

Fig. 3. Naphthalene crystal (001) face etched with cold water. Oblique illumination ( $\times c. 135$ ).

to the melting point of the solid can result in a marked reduction in dislocation content. Intentionally doped crystals contain a higher concentration of dislocations than the pure crystals. A noticeable factor in the case of the doped crystal was the greatly increased number of sub-grain boundaries compared with the pure crystal. These observations are in accord with the results of recent investigations of the effects of doping on the physical properties of aromatic solids. More detailed publications dealing with these aspects will appear shortly.

## APPLIED SCIENCE

### Buffer Electrolytes for Fuel Cells

SULPHURIC acid, phosphoric acid and concentrated caustic solutions are the electrolytes most frequently used in the development of fuel cells, but they have disadvantages which justify the investigation of substitutes. The chief disadvantage of caustic electrolytes is their inability to reject carbon dioxide when a carbonaceous fuel is completely oxidized. Considering electrolyte invariance and ionic concentration polarization only, Williams and Gregory<sup>1</sup> recommend strong acid electrolytes for low temperature fuel cells. Acids, however, present a severe corrosion problem. Thus, fuel cells using acid electrolytes require noble metal catalysts, not only for catalytic activity, but also to withstand corrosion. The electrode supports must also either be a noble metal or a costly non-noble corrosion resistant metal such as tantalum. Cairns and MacDonald<sup>2</sup> have shown the feasibility of highly soluble carbonates as invariant electrolytes for fuel cells, although temperatures ranging from 130° to 200° C appear to be necessary. This communication shows that other choices of electrolyte are possible which may eliminate some of these problems.

A suitable electrolyte must exhibit many of the properties of strong acids and bases. In particular, a property of acids and bases frequently overlooked in fuel cell work is their excellent buffering ability. This is a necessary property because the potentials of both electrodes of a fuel cell depend directly on the electrolyte pH at the interface. Changes in pH, caused by current flow, at the interface are manifested as polarizations over and above activation and ohmic polarizations. Thus, buffering is necessary to minimize interfacial pH changes, so that buffers are the only possible substitutes for strong acids or bases.

Buffers can be selected which function at a pH where carbon dioxide is rejected. The electrolyte reactivity which plagues caustic pH electrolytes is then no longer a problem. In addition, corrosion is generally less severe in the intermediate pH range, so that buffers could make it possible to use non-noble metals as fuel cell components.

It remains to be shown, however, that appreciable activities can be obtained in the intermediate pH range. Although little work in fuel cell development has dealt with intermediate pH electrolytes, barring specific effects at a given pH, such as adsorption limitations, there is no *a priori* reason why activity should not be elicited over the entire pH spectrum. Tests were therefore conducted on the activities obtainable with buffer electrolytes using a typical fuel and oxidant.

Methanol is a carbonaceous fuel that has been anodically oxidized at a platinum black electrode, in strong acid and base electrolytes. Table 1 shows that methanol is also active in the weakly acid or nearly neutral pH range as well as in the weakly alkaline region. Carbon dioxide was rejected in all cases.

Table 1. ANODIC OXIDATION OF METHANOL AT 60° C OVER pH RANGE OF TEN UNITS

75	0.51	0.53	0.71	0.44
100	0.52	0.50	0.73	0.46

\* Polarization is defined as the departure of the electrode potential from the reversible value under the same conditions of temperature, pressure and concentration.

The poor performance of methanol in sodium sulphate solution contrasts sharply with the anodic activity shown in the phosphate buffer at practically the same pH, and in the carbonate buffer 4 pH units removed. These results

show that buffering capacity rather than pH is the important criterion for electrolyte selection.

Stirring the electrolyte has no effect on the performance in 3.7 molar sulphuric acid, but can improve performance in phosphate and carbonate buffers by as much as 40 mV at 100 m.amp/cm<sup>2</sup>. This difference is due to the greater buffering capacity of 3.7 molar sulphuric acid and not to limitations on methanol diffusion. The improvements in performance when an unstirred but more concentrated buffer is used are the same as those accomplished by stirring in a more dilute buffer solution. Thus, with a soluble fuel in concentrated buffer solution, concentration polarization is virtually eliminated.

Although electrode structure is more critical with gaseous than with soluble reactants when buffer electrolytes are used, respectable levels of performance can still be attained. Table 2 shows the performances achieved with oxygen on an interface maintaining platinum-'Teflon' electrode.

Table 2. CATHODIC PERFORMANCES IN BUFFER ELECTROLYTES AT 60° C

Geometric current density m.amp/cm <sup>2</sup>	Volts polarized from theoretical oxygen			
	8.7 M H <sub>2</sub> SO <sub>4</sub>	1 M KH <sub>2</sub> PO <sub>4</sub> 1 M K <sub>2</sub> HPO <sub>4</sub>	2 M RbH <sub>2</sub> PO <sub>4</sub> 2 M Rb <sub>2</sub> HPO <sub>4</sub>	1 M KHCO <sub>3</sub> 1 M K <sub>2</sub> CO <sub>3</sub>

50	0.31	0.47	0.46	0.42
75	0.32	0.55	0.52	0.47
100	0.33	0.61	0.56	0.53
150	—	—	0.66	—

The poorer oxygen performances with the buffer electrolytes are mainly due to the greater concentration polarizations incurred with these electrolytes and diffusion electrodes. Increasing the buffer concentration, of course, reduces concentration polarization, and substantial improvements in performance at a cathode can be effected by increasing the buffer concentration (Table 2).

In comparing the performance of methanol and oxygen in the various electrolytes, the following conclusions can be drawn. Where the electrode is in direct contact with the bulk electrolyte, as when a soluble fuel is used, buffer electrolytes can be substituted for strong acids with little additional concentration polarization. At an electrode that has to maintain a three-phase interface, however, ionic mass transfer can occur solely by molecular transport (diffusion and conductance). Because of the abnormally high mobility of hydrogen and hydroxide ions, acids and bases are, therefore, more efficient than buffers in minimizing concentration polarization at interface maintaining structures.

A fuel cell using buffer electrolytes could therefore not match the power density the same cell would exhibit if a strong acid or base served as the electrolyte. In addition to the greater concentration polarization exhibited in buffer, the ohmic loss in the cell would be higher than these losses would be with acid or basic electrolytes. Assuming that activation polarization is identical in all the electrolytes, the cell operating with buffer electrolyte obviously has a smaller power output. Fuel cells of lower power density, however, could be acceptable substitutes, provided the buffers would allow the use of inexpensive non-noble metal catalysts.

Part of this work was made possible by support from the Advanced Research Projects Agency through the U.S. Army Electronics Laboratories.

## Mechanism of Coal Decomposition

DAVIES<sup>1</sup> has studied the thermal decomposition of a bituminous coal, and has laid particular emphasis on the heat flux to the coal particles. Individual spheres of coal were suspended from a recording balance in a stream of hot nitrogen. To begin with, the weight record showed a constant rate of loss and in the final part the rate of weight loss decreased with time. The initial constant rate of weight loss was found to be directly proportional to the heat flux and was zero at about 400° C.

For a system with heat transfer by forced convection, the heat flux to a particle is given by

$$Q = hA(T_g - T_s) \quad (1)$$

where  $h$  is the heat transfer coefficient;  $A$ , the surface area of the particle;  $T_g$ , the gas temperature; and  $T_s$ , the surface temperature of the particle.

In the experiments reported here, particle diameter  $D$  and therefore area  $A$ , gas temperature  $T_g$  and gas flow rate were varied in order to vary the heat flux.

For the initial period of constant rate of loss of weight the surface temperature was estimated to be constant at about 400° C, by extrapolation from measurements with thermocouples at different distances below the surface of slabs of coal. A surface temperature of 400° C has also been reported for coal combustion during the initial "volatile" combustion period<sup>2</sup>.

The heat transfer coefficient,  $h$ , was obtained from the correlation<sup>3</sup>

$$\frac{hD}{K} = 2.0 + 0.6 (Re)^{1/2} (Pr)^{1/3} \quad (2)$$

where  $K$  is the particle thermal conductivity;  $Re$ , the Reynolds number; and  $Pr$ , the Prandtl number.

The heat transfer coefficient was changed by varying the gas temperature in the range 350°–550° C; by varying the rate of gas flow in the range 40–400 ft.<sup>3</sup>/h; and by varying particle diameter in the range 0.25–1 in.

To test the hypothesis that loss of weight depends directly on heat transfer, the initial, constant, rate of weight loss was plotted against (1) the gas temperature, for constant Reynolds number and particle diameter; (2) the square root of the Reynolds number, for constant particle diameter and gas temperature; (3) the particle diameter, for constant gas temperature and Reynolds number.

Straight lines were obtained in each case, an indication that the initial rate of weight loss is determined by heat transfer.

Most of those who have studied the kinetics of isothermal coal decomposition have suggested that chemical reactions are rate-controlling. Some of the "activation energies" quoted, however, 2–15 kcal/mole, appear to be too low to refer to the breaking of chemical bonds. Higher values have been obtained but they have come mainly from the analysis of weight losses measured only after the loss of most of the volatile material. Peters<sup>4</sup>, however, suggested that the rate of weight loss is controlled by the rate of a physical process. He also noted the similarity between weight loss curves for coal decomposition and the drying of granular material.

To summarize, it is suggested that the controlling factor in the initial stages of isothermal decomposition of bituminous coal particles is the rate at which heat can be transferred to the particles. This heat is absorbed during endothermic degradation reactions and in the removal of liquid and gaseous products.

The rate of weight loss is given by the equation

$$\frac{dW}{dt} = \frac{hA(T_g - T_s)}{\lambda}$$

where  $\lambda$  is 1,700 cal/g and  $T_s$  is 400° C for the coal used.

We thank the National Coal Board for a grant in aid of this research.

## CHEMISTRY

### Thermoluminescence from Recombination of Organic Ions

THE trapping of positive and negative ions in  $\gamma$ -irradiated organic glasses at 77° K has been extensively studied by Hamill *et al.*<sup>1</sup> The products of the recombination of ions are of considerable interest in the elucidation of reaction mechanisms in radiation chemistry. We have shown previously<sup>2</sup> that ion recombination in solutions of naphthalene in a hydrocarbon glass (2 parts methyl-cyclohexane : 3 parts isopentane) leads to luminescence on warming—thermoluminescence (TL)—or on stimulation by infra-red radiation (IRSE). This work has been extended and we report here some new results.

A more careful estimate of the thermoluminescence yield leads to a  $G$  value for emitted quanta of the order of magnitude of 0.1: our previous estimate<sup>2</sup> of 10<sup>-6</sup> (based on the manufacturer's data for the photomultiplier sensitivity) was in error—the result partly of a faulty photomultiplier circuit and partly of a numerical mistake in the calculations: the new value depends on a comparison of the intensity of thermoluminescent emission with a standard scintillation solution containing carbon-14 (ref. 3). The  $G$  value for trapped ions is about 1: because the luminescence yield of excited naphthalene is low<sup>4</sup>, the majority of the recombining ions probably produce excited states. Luminescence is therefore a useful tool for studying ion recombination in this system.

Further study of the emission spectrum has shown that in addition to naphthalene fluorescence and phosphorescence, emission from the excimer<sup>5</sup> ( $C_{10}H_8$ )<sub>2</sub><sup>+</sup> also occurs. This band was at first thought to be caused by the solvent, but the band is narrower than the emission spectrum of the impure solvent and its intensity increases rapidly with increasing concentration (maximum used was 10<sup>-2</sup> molar). The excimer band is stronger in TL than in IRSE; this probably accounts for the apparent difference in phosphorescence/fluorescence ratio described previously<sup>2</sup> as the filter used to measure fluorescence intensities also transmitted the excimer band.

In addition to  $C_{10}H_8^-$  and the  $C_{10}H_8$  radical, we have now detected  $C_{10}H_8^+$  (ref. 6) in the visible absorption spectrum after irradiation. At low solute concentrations (for example, 10<sup>-4</sup> molar) in hard glasses, trapped electrons can be detected by their infra-red absorption<sup>1,2,7</sup>, but at 10<sup>-2</sup> molar concentration the only negative species observed was  $C_{10}H_8^-$ ; therefore it seems reasonable to suppose that luminescence results from recombination of  $C_{10}H_8^+$  and  $C_{10}H_8^-$  which diffuse together on warming the solvent. Because emission is observed both from excimers and single molecules, it is possible that the negative ion dissociates into  $C_{10}H_8$  and an electron during the diffusion process (perhaps as a result of the field of the positive ion). The previously suggested reaction between  $C_{10}H_8^-$  and a solvent cation, however, cannot yet be ruled out. The concentration dependence<sup>2</sup> of the yield of TL remains puzzling.

Johnson and Albrecht<sup>8</sup> have recently shown that  $CO_2^-$

may play an important part in the photolysis of similar glassy solutions because carbon dioxide is not removed by the usual freeze-pump-thaw degassing procedure. Experiments with added carbon dioxide and with solutions degassed by bubbling pure nitrogen through them show that our previous results were not affected by the presence of carbon dioxide: naphthalene competes efficiently for the electrons. Addition of large amounts of carbon dioxide (several hundred mm of mercury), however, removes the  $C_{10}H_8^-$  absorption leaving  $C_{10}H_8^+$ : TL is somewhat weakened and consists of phosphorescence alone. This suggests that recombination of  $C_{10}H_8^+$  with  $CO_2^-$  can lead to excitation, but there is insufficient energy available to produce the excited singlet state. The singlet and triplet excitation energies are 3.9 and 2.6 eV. The electron affinity of carbon dioxide (or, rather, the vertical ionization potential of the ion) has been estimated to be between 2.3 and 2.9 eV<sup>9</sup>. The ionization potential of  $C_{10}H_8$  is 8.1 eV in the gas phase<sup>9</sup>: it may be 1–2 eV less in solution. This leaves 4.2–5.8 eV for recombination, which may be further reduced if coulombic energy is lost in collisions during the approach of the ions.

### Kinetics of Proton-transfer Reactions

THE kinetics of proton-transfer reactions have been studied, using a number of methods, by Eigen *et al.*<sup>1</sup> and by Ertl and Gerischer<sup>2</sup>, and this communication reports the application of yet another technique—pulse radiolysis—to the study of the reaction between  $H_3O^+$  and  $OH^-$ .

Pulse radiolysis of water and aqueous solutions produces transient changes in composition, and the subsequent relaxation of the system can be studied in various ways, for example, by measuring the electrical conductivity. The latter method is, of course, applicable only to reactions involving ionic species. In irradiated water the ionic products are  $H_2O^+$ ,  $H_2O^-$  and  $OH^-$  and the behaviour of the hydrated electron ( $H_2O^-$ ) has been extensively studied by absorption spectroscopy<sup>3</sup>. Conductimetry, however, can be applied to all these ions and thus, in conjunction with pulse radiolysis, can be used to study fast homogeneous reactions involving  $H_3O^+$ . The overall effect is the sudden production of these three ionic species (along with uncharged radicals) and the relaxation of the  $H_3O^+$  concentration can be followed under appropriate conditions.

In dilute ammonia the hydrated electron is relatively long lived, and if the concentration of  $OH^-$  is substantially larger than those of the  $H_3O^+$  and  $OH^-$  produced by

radiation, the observed decay in conductivity can be ascribed to the pseudo-first order reaction of  $\text{H}_3\text{O}^+$  with  $\text{OH}^-$ . Pure water and dilute aqueous ammonia were accordingly irradiated with 2.5  $\mu\text{sec}$  pulses of 4 MeV electrons from the linear accelerator at Wantage Radiation Laboratories, and the change in electrical conductivity with time was recorded. Doubly distilled water was used. In the second stage mildly oxidizing conditions were maintained in the still pot, carbon dioxide was rigorously excluded and a stream of purified argon was used to purge carbon dioxide from the system. The distillate was condensed in a silica condenser, collected in a silica flask saturated with hydrogen and blown through the conductivity cell with hydrogen under pressure. 0.05 molar ammonium hydroxide was added to bring the final concentration of  $\text{OH}^-$  to  $1.5 \times 10^{-6}$  molar. As produced, the water had a specific conductivity of about 1.3 times the value computed for pure water and the value was only slightly higher in use. Adequate purity in the radiation chemical sense was inferred from the observation that irradiation had no long term effect on the conductivity. Indeed, conductivity changes due to successive electron pulses  $\sim 3$  msec apart were identical within the limits of reproducibility of the accelerator. Attempts to clean up the water by pre-irradiation produced no change in the conductivity waveform.

The conductivity cell, made of 'Pyrex' and platinum, had three electrodes of 0.001 in. platinum and a window of 0.02 in. 'Pyrex' all perpendicular to the axis of the electron beam (Fig. 1a). The electrodes were 2.5 mm apart, the first being close up against the window, and the electron beam was 1 cm in diameter at the window. The change in conductivity was measured by applying a pulse of about 800 V to the outer two electrodes and then comparing the current received by the central electrode with that induced in a circuit simulating the cell. The difference signal due to the change in conductivity was displayed on a Hewlett-Packard oscilloscope.

A typical oscillogram is shown in Fig. 1b. It can be seen that long term effects after the initial decay due to the loss of  $\text{H}_3\text{O}^+$  and  $\text{OH}^-$  are negligible. The fact that the conductivity increase has disappeared after 60  $\mu\text{sec}$  when hydrated electrons are still present is due to the almost identical equivalent conductivity of  $\text{H}_2\text{O}^-$  and  $\text{OH}^-$  (ref. 4). This means that replacement of  $\text{OH}^-$  ions present before the pulse by  $\text{H}_2\text{O}^-$  after the initial decay produces no change in the conductivity. The plot of log conductivity change against time is shown in Fig. 1c (taken from the oscillogram in Fig. 1b). A straight line is obtained indicating pseudo-first order kinetics. The value of the

Fig. 1.

$\text{OH}^-$ (moles/l.) $0.93 \times 10^{-4}$	$\text{H}_3\text{O}^+$ (moles/l.) $0.94 \times 10^{-7}$	$t$ ( $\mu\text{sec}$ ) 15	$k\text{H}_3\text{O}^+ + \text{OH}^-$ (moles $^{-1}$ sec $^{-1}$ ) $7.2 \times 10^{10}$
1.03	$0.94 \times 10^{-7}$	13.5	7.5
1.03	$1.7 \times 10^{-7}$	13.5	7.2
2.82	$1.7 \times 10^{-7}$	4.8	7.4
3.75	$1.7 \times 10^{-7}$	3.8	7.0

Mean 7.3

For these experiments the temperature was  $15^\circ \pm 1^\circ \text{C}$  and at this temperature Ertl and Gerischer obtain  $k = 1.16 \times 10^{11}$  moles $^{-1}$  sec $^{-1}$ .

rate constant obtained in this way is listed in Table 1 along with other values at different concentrations and compared with the value given by Ertl and Gerischer.

It is clear that the value obtained in these pulse radiolysis experiments is appreciably lower than that from other methods and it is pertinent to examine possible sources of error, although it seems unlikely that a linear plot (Fig. 1c) would be obtained if the observed decay were due to a combination of processes. In some cases curvature was observed at longer times but could be attributed to much slower processes (due presumably to traces of oxygen) and allowed for in the calculation of the rate constant.

Second order reactions would contribute little to the observed decay as all the radiation-produced species would be at the same or at lower concentrations than  $\text{H}_3\text{O}^+$  as listed in Table 1 and calculated from the conductivity peak in pure water. As the  $\text{OH}^-$  concentration falls due to reaction with  $\text{H}_3\text{O}^+$ , more is produced from the undissociated ammonium hydroxide, but though the relaxation time<sup>6</sup> is smaller than the time constant of the  $\text{H}_3\text{O}^+ - \text{OH}^-$  reaction, the amount produced would be too small to make an appreciable difference to the observed decay.

The applied field of about 2 kV/cm was too low to cause field dissociation of water or ammonium hydroxide. The ions are not produced uniformly, but it is difficult to see how a slightly uneven distribution could give too low a value of  $k$ .

At the moment, then, it does not seem possible to reconcile the results reported here with those obtained using other techniques. Further work is under way to improve the signal to noise ratio and to study other systems.

## Glow Phenomenon of Chromium Oxide

CHROMIUM oxide is used extensively as a catalyst, both as the pure oxide and as an essential component of various multicomponent systems. The unsupported chromium oxide gel usually undergoes a strongly exothermic transformation, or "glow phenomenon", when heated in air at a temperature of about  $400^\circ \text{C}$ . The evolution of heat is accompanied by the development of the crystalline phase of  $\alpha$ -chromium oxide and a diminution in catalytic activity<sup>1,2</sup>; the existence of the glow phenomenon therefore imposes severe limitations on the use of the unsupported oxide as a catalyst.

The reason why crystallization of the hexagonal form occurs at the relatively low temperature of  $400^\circ \text{C}$  is still not clear. Comparison with aluminium oxide suggests that a temperature of over  $1,000^\circ \text{C}$  would be required before drastic crystallization of the corundum structure occurs, and it would appear that there is a special mechan-

ism for chromium oxide. According to Burwell *et al.*<sup>3</sup>, if a chromium oxide gel is heated cautiously the glow phenomenon can be avoided, and once safely taken to a temperature greater than 400° C the gel is then more stable than the material dried at a lower temperature. Differential thermal analysis was used, to show that a chromium oxide gel heated in an atmosphere of nitrogen fails to exhibit an exothermic peak up to a temperature of 600° C, but that the exothermic reaction occurs if air is admitted to the sample at this temperature<sup>4,5</sup>. It was concluded that the crystallization of chromium oxide is facilitated by an oxidizing atmosphere. It has been established<sup>6</sup> that chromium (IV) is formed (at least at the surface) on heat treatment of a chromium oxide gel, although no adequate explanation has been given for the part played by the higher oxidation state in connexion with the glow phenomenon.

We have investigated changes in the bulk and surface properties of various chromium oxide gels in an attempt to establish the conditions in which the glow phenomenon can be prevented, and to elucidate the mechanism of the process. It is now evident that the treatment advocated by Burwell is inadequate unless certain other conditions are fulfilled.

The differential thermal analysis curve in Fig. 1 was determined on a chromium oxide gel which was prepared by heating an aqueous solution of chromium (III) nitrate with urea<sup>3</sup>; the curve was obtained by heating the sample in an oxygen atmosphere at the rate of 5°/min. A broad endothermic peak is intersected by two exothermic peaks, one at about 230° C and the other at about 280° C, and the glow phenomenon is manifested by the sharp exothermic peak at 400° C. No significant change was observed by heating in air in place of oxygen, by using a dry or damp atmosphere, or by varying the rate of heating from 2°–10°/min. Heating in an atmosphere of nitrogen, however, did give a different differential thermal analysis curve (Fig. 2); the exothermic peak at 280° C is almost eliminated and the glow phenomenon is delayed until a temperature of about 580° C is reached. Change in the rate of heating again had little effect, and a curve similar to that shown in Fig. 2 was also obtained *in vacuo*. Results of differential thermal analysis on other chromium oxide gels were broadly similar to those shown in Figs. 1 and 2, although the exact location and the intensity of each peak depended on the preparation of the gel. It is clear that heating in nitrogen or *in vacuo* does not eliminate the glow phenomenon, but does suppress it until the temperature reaches at least 500° C; admission of air or oxygen, on the other hand, causes the glow to occur if the temperature is above 400° C.

In view of these observations, it was of interest to investigate heat treatment in a reducing atmosphere to

Fig. 1. Differential thermal analysis of chromium oxide gel in oxygen (rate of heating, 5°/min).

Fig. 2. Differential thermal analysis of chromium oxide gel in nitrogen (rate of heating, 5°/min).

Fig. 3. Differential thermal analysis of chromium oxide gel in air (rate of heating, 5°/min), after initial heat treatment in oxygen for 8.5 h at 300° C.

ascertain whether the glow could be avoided. The phenomenon occurred at about 420° C, even after 3 h in the temperature of 300°–350° C. This result suggests a different mechanism from that applying when the crystallization occurs in an oxidizing atmosphere. We soaked the sample in an oxidizing atmosphere at a temperature lower than 400° C, to permit as much oxidation as possible below the "glow" temperature. It was then possible to prevent the glow phenomenon if the sample was held for 3 h at 350° C, but not if the preliminary heat treatment was maintained for up to 8.5 h at 300° C. Fig. 3 shows that the exothermic transformation at 400° C is resolved in these conditions into two peaks, one at 405° C and the other at 420° C, which indicates a two stage process.

The conversion of chromium oxide gel to macro-crystalline  $\alpha$ -chromium oxide appears to occur most readily (that is, to require the minimum amount of thermal energy) when the solid is subjected to a steadily increasing temperature in an oxidizing atmosphere. In such conditions, the oxidation of Cr (III) to Cr (VI) (and possibly also to one or both of the intermediate oxidation states) must promote the glow phenomenon. Radiochemical exchange experiments suggest that surface oxidation probably takes place at temperatures below 300° C, but there is clearly an additional process which probably involves penetration of oxygen through the outer layers of the solid. This oxidation process occurs fairly slowly at 350° C and rapidly at 400° C, and the difference in rate

is perhaps the most important factor in the control of the glow phenomenon. It appears that the slow oxidation at 350° C provides insufficient localized heating to overcome the energy barrier associated with the reorganization of the solid structure to the lattice of the  $\alpha$ -chromium oxide, whereas the more rapid release of heat at 400° C is sufficient to initiate the crystallization process, which in turn liberates more heat and results in an overall reduction. In accordance with these ideas, the glow phenomenon when it takes place in an oxidizing atmosphere is made up of two stages, which usually overlap giving rise to a large and continuous release of energy. When the secondary oxidation is reduced in extent or in rate, however, the two stages may be separated (Fig. 3).

It is impossible to state the proportion of the chromium oxide system which is converted to the higher oxidation state, but probably the catalytic activity (at least for certain reactions), the black appearance and the semiconductor properties all depend on the presence of two or more oxidation states in a defect structure. Prevention of the glow phenomenon is, therefore, important, not only because it results in crystal growth and loss of specific surface area<sup>3,7</sup> (recent work indicates that the rate of loss of surface area is not especially high at 400° C), but essentially because the overall reduction to  $\alpha$ -chromium oxide alters profoundly the electronic properties of the gel.

### Recovery of Iodide- $I^{131}$ from Aqueous Solutions of pH 5

I HAVE found an unexpected dependence on the amount of carrier iodide<sup>1,2</sup> of the recovery of radioactive iodide by solvent extraction of its aqueous solutions to which sodium nitrite has been added. The percentage recovery of the radioactive iodide by the solvent is inversely proportional to the amount of iodide in solution if the pH is between 4 and 7. The relationship is linear for the range of concentrations of iodide which were tested, 0.01  $\mu$ g to 0.1  $\mu$ g, and the coefficient of variation of experimental results at the mid-point of the range was  $\pm 4$  per cent.

The procedure used was initiated by the addition of 1.0 ml. of a normal sodium nitrite and 4.0 ml. of sodium acetate and acetic acid buffer, pH 5.0, to an aqueous solution containing 10  $\mu$ c. of iodide- $I^{131}$  and a known amount of iodide as potassium iodide; the final aqueous volume was 14 ml. Solvent extraction was then carried out using 4.0 ml. of benzene and the radioactivity in this extract was compared with that of the initial radioactive iodide solution.

The result is given by this relationship:

reciprocal of percentage recovery of  $I^{131}$  =  $S$  per cent<sup>-1</sup>  $\mu$ g<sup>-1</sup> ( $I$  -  $\mu$ g) +  $K$  per cent<sup>-1</sup>

$S$ , the sensitivity, varies from 0 per cent<sup>-1</sup>  $\mu$ g<sup>-1</sup> at pH 4 to 16 per cent<sup>-1</sup>  $\mu$ g<sup>-1</sup> at pH 5, while at pH 7, although the sensitivity is high, the recovery was too low for accurate measurement. The value of  $K$  at pH 5 is 0.7 per cent<sup>-1</sup>.

When acetate buffer at pH 5 was used, results identical to those given in experiments conducted at the same pH without buffer were obtained.

The radioactive iodide was shown to act in its intended capacity as a radioactive label. The only effect of an increase in the amount of radioactive iodide was an increase in the blank value,  $K$ , in accordance with the known carrier content of the radioactive iodide solution. The change which was observed in the value of the sensitivity,  $S$ , from 9 per cent<sup>-1</sup>  $\mu$ g<sup>-1</sup> for freshly diluted radioactive solution, to 16 per cent<sup>-1</sup>  $\mu$ g<sup>-1</sup> for solution which had been diluted for 21 days, implies the degradation of the radioactive iodide into other species which do not take part in the reaction. The radioactive iodide solution was prepared in 0.02 normal sodium hydroxide by dilution of the commercially supplied solution which contains sodium thiosulphate as a stabilizing agent.

The function of the benzene was shown to be that of an extracting solvent and not that of an active reagent<sup>3</sup>. Other solvents were tried, but absorption on glassware decreased the linearity and accuracy of the results. Reproducible results could only be obtained by a strict control of the time sequence of operations. It was also necessary to wash the glassware with "chromic acid" and to follow this with a thorough rinsing with distilled water. The interference of chloride was found to be negligible in one experiment, in which 40 mg of chloride, as sodium chloride, was added to each of the iodide solutions.

I suggest that the basic mechanism of the procedure is the oxidation of iodide by nitrite to elemental iodine. The inverse relationship between the recovery of radioactive iodide and the amount of iodide implies that an isotopic dilution effect occurs and that a constant amount of iodine is extracted. The sensitivity of the procedure and the linearity of the results suggest the possibility of developing an analytical method for the determination of sub-microgram quantities of iodine.

I thank Professor F. W. Spiers for his initiation and encouragement of this work and the Medical Research Council for their financial support.

### Electronic Absorption Bands associated with the Hydrogen Bondings of Thymine and Uracil

IN the course of investigations of the electronic absorption spectra of crystals of DNA bases, we have found that an unusual band appears in addition to the usual  $\pi \rightarrow \pi^*$

transition when the crystal has the

hydrogen bonding. This absorption band is observed in thymine monohydrate, thymine, uracil and 5-ethyl 6-methyl uracil crystals; however, it is not found in calcium thymidylate and barium uridylate<sup>1</sup>. In the former class of crystals, hydrogen bondings of the type

Fig. 1. *a*, Crystal absorption spectrum of thymine monohydrate taken with (010) face, and light polarized parallel to the  $Z'$  and  $X'$  axis—the former axis is the slow direction and the latter the fast optic axis. *b*, Projection of thymine molecules on to (010) plane. The optic axes are shown.

are present, while in the latter such bondings are not present, because the bases are separated from each other. Fig. 1*a* shows a typical absorption spectrum for a crystal of thymine monohydrate; for comparison, Fig. 2 shows the absorption spectrum of calcium thymidylate. Both compounds show similar absorption spectra in solution at about 2640 Å, and corresponding bands occur at about the 2600~2750 Å region in all such crystals. The extra band at 2850 Å in thymine monohydrate crystals is considered to be a new type, because it is observed only in the particular crystalline state. It was possible to determine the direction of the transition moment of the 2650 Å band ( $\pi \rightarrow \pi^*$  transition) from the polarization measurement of all these crystals. It was found to be inclined at about 20° from the  $N_1$  - -  $C_4$  line towards  $N_3$  atom (compare with Fig. 3). This result is nearly in agreement with the earlier results of Stewart and Davidson<sup>2</sup> on 1-methyl thymine, who regarded this angle to be either 14° or -19°.

The new specific band at 2850 Å has a different polarization property, as shown in Fig. 1. The direction of the

transition moment has been found to be in the direction of the hydrogen bonding between a pair of

groups. From a comparison with the 2650 Å band it would seem possible that the molar extinction coefficient of this band might be several thousand. With regard to the assignment of this band, the following points should be considered. (i) The new band can only be detected when the system has hydrogen bonding of the type

between the base pairs, and therefore it should be intimately connected with the hydrogen bonding. Alternative explanations, such as the Davydov-type band splitting in crystals, can be rejected because the band is observed both along the  $b$ -axis and  $a,c$ -axis directions, and this could not occur when the crystalline selection rule is dominant. (ii) The electronic origin of this transition might be not a  $\pi \rightarrow \pi^*$  type, because the parent absorption band is only slightly influenced by the occurrence of the new band. This suggests that the band does not arise from the  $\pi$ -electron interaction between the base pairs, but it is probably related to the non-bonding electron of

Fig. 2. Crystal absorption spectrum of calcium thymidylate taken with (010) plane and light polarized parallel to the  $b$  and  $c$  axes.

Fig. 3. The direction of transition moment of 2600 Å band ( $\pi \rightarrow \pi^*$  transition).

the oxygen atom and  $\sigma$ -orbital of the N—H bond. (iii) The  $n \rightarrow \pi^*$  transition of the carbonyl group should have a different polarization perpendicular to the ring plane. All these considerations lead us to the conclusion that the band is intimately related to the charge transfer interaction in hydrogen bonding.

The significance of charge transfer force in hydrogen bonding was first pointed out by Nukasawa, Tanaka and Nagakura<sup>3</sup> and further discussions are given by Tsubomura<sup>4</sup> and Coulson and Danielsson<sup>5</sup>. The charge transfer band in hydrogen bonding system was first recognized by Nagakura<sup>6</sup> in hydrogen maleate ion. In the present system the resonance structures of (I), (II) and (III) will be important,

and as a result of the resonance interaction between these structures, both stabilized ground and excited states will be produced. The transition between the ground state and the excited state will be possible when the electric vector of light vibrates along the hydrogen bonding. The location of the new band will depend on both the diagonal energy levels of structures (II) and (III) relative to (I) and the off-diagonal matrix elements. The numerical estimates of these values are rather difficult at the moment; however, the observed value of 2850 Å is certainly reasonable on the basis of the foregoing interpretation. We may therefore designate it an "intermolecular charge transfer absorption of hydrogen bonding" because structure (III) will be predominant in the lowest excited configuration.

This work was supported by a grant from the Ministry of Education, Japanese Government, and we thank Dr. R. E. Marsh, of California Institute of Technology, for a gift of the sample.

## MOLECULAR STRUCTURE

### New Approach to Structure Studies in Organic Chemistry

We have already reported some applications of electron spectroscopy in the study of chemical binding<sup>1</sup>. We showed that the shifts of the electron lines of an element can be correlated with its chemical state of oxidation. Our method makes use of Auger and photo electrons produced by X-rays and is called ESCA (electron spectroscopy for chemical analysis). Most of the results reported were obtained from the element sulphur, and electron spectra from this element have, for example, been used to solve a specific problem concerning the molecular structure of cystine S-dioxide<sup>2</sup>.

For a more general study of structure problems in organic chemistry by the ESCA method special importance

is naturally attached to the element carbon. This communication reports the first results to show that electron spectra from carbon are actually related to the molecular structure. We have chosen the compounds

both of which were irradiated with aluminium X-radiation. Fig. 1 shows the electron spectra obtained from these compounds. Electron lines from the constituent elements sodium oxygen and carbon are seen in the spectra, and the counting rate is high, although the elements all have low atomic numbers and hence small photoelectric cross sections. The line widths obtained are essentially the inherent widths of atomic levels.

The most striking observation is the fact that carbon gives two well separated lines, the energy difference being 3.8 eV in 1,2,4,5-benzenetetracarboxylic acid and somewhat less in sodium benzoate. The relative intensities of the two lines in the compounds are 4:6 and 1:6 respectively, which means that the low energy line corresponds to the carboxyl carbon atom and the other to the benzene carbon atom. The electron spectrum of carbon thus maps out very clearly the relative number of carbon atoms in the benzene ring and in the carboxyl groups that are attached to the ring. The finding that the carboxyl line has lower energy in the electron spectrum is consistent with the fact that the electronegativity of oxygen is higher than the electronegativities of both carbon and hydrogen. Because oxygen is more electronegative, there will be less negative charge within a certain atomic distance around the carbon nucleus in a carboxyl group than within the same distance around a carbon nucleus in the benzene ring. The electrostatic shielding of the 1s electron is therefore smaller for the carboxyl carbon and the binding energy of 1s electrons becomes larger, as can be seen in the electron spectrum. More detailed information on the molecular structure can be obtained from a

Fig. 1. ESCA spectra of 1,2,4,5-benzenetetracarboxylic acid and sodium benzoate. The electron spectra are obtained using aluminium K $\alpha$  radiation and contain both photo electron and Auger lines from the constituent elements of the compounds. In the upper part of the figure the carbon 1s level is shown to split up into two well separated components, with an energy difference of 3.8 eV. The line to the left corresponds to the 1s level in the carboxyl carbon. The relative intensities of the two lines are 4:6, in agreement with the structural formula. In the lower part of the figure a double carbon line can be seen. The intensity ratio between the two components is in this case 1:6, as expected from the structural formula. A comparison of the line shapes and line strengths of the oxygen lines in the spectra shows that the oxygen line in the carboxyl group is actually composed of two components each with the same intensity. The separation between the components is 1.1 eV.

discussion of the absolute line positions in the electron spectrum and a closer analysis of the benzene carbon line.

Comparison of the oxygen lines from the two compounds reveals a structure effect similar to that observed for carbon. The oxygen line widths in the two compounds are 3.1 eV and 1.8 eV. The broader of these lines can be resolved graphically in two components of equal intensity and half width 1.8 eV, and with a separation of 1.1 eV. The intensity ratios between carbon and oxygen in the two compounds, obtained from the areas under the lines, are consistent with the ratios calculated from the empirical formulae of the compounds.

We have recently observed large chemical structure effects in other organic compounds, in which the 1s electron line from nitrogen is observed to be split in components that differ by as much as 6.2 eV. This is an appreciable shift which is of the same order of magnitude as, for instance, the energy difference between the 2s and 2p atomic sub-shells in nitrogen.

There seems to be good reason to believe that the chemical structure effects in the electron spectrum of carbon and other elements which we have observed can be used in solving many structural problems in organic molecules.

We thank Bernt Lindberg of the Research Division, Pharmacia AB, for valuable discussions.

## X-ray Evidence of Regularly Distributed Lysine in $\alpha$ -Keratin

INVESTIGATIONS of the low angle X-ray diffraction patterns of various  $\alpha$ -keratins have established the presence of structural regularities with an axial pseudo-period of 198 Å (ref. 1). Evidence of chemical reactivity associated with longitudinal periodicity was first obtained by Kratky *et al.*<sup>2</sup>, who noted the appearance of intense low-angle meridional reflexions in human and horse hair which had been treated with nitric acid. Apart from a partial decomposition of the keratin, the main chemical effect of this treatment is nitration of the tyrosine residues.

In Lincoln wool an isomorphous replacement of tyrosine residues by 3,5-diiodo-tyrosine residues<sup>3-5</sup> intensifies the sixth order of the 198 Å repeat. Another axial periodicity of amino-acid residues in  $\alpha$ -keratin has been found<sup>7</sup> by specific staining of cystine in the tips of porcupine quills. A sample in which the more reactive fraction of the cystine was reduced and cross-linked with ethylene dibromide and the least reactive fraction was reduced and reacted with methyl mercuric iodide gave considerable intensification of the third order of 198 Å. These results suggest a regularity of tyrosine and cystine residues in the microfibrils.

In the structural units there is probably a periodic arrangement of lysine residues, for the basic amino-acids tend to occur in clusters rather than evenly distributed

along the peptide chains<sup>8</sup>. It was therefore interesting to see whether there is X-ray evidence for a regular distribution of lysine in the microfibrils. According to Zahn *et al.*<sup>9-11</sup>, the nitrophenylesters of carboxylic acids react with the side-chains of lysine only. This reaction introducing N-acetyl groups includes the possibility of labelling lysine residues specifically. Mohair gives the best X-ray pattern of all keratin fibres examined and so this material was chosen for chemical modification with the *p*-nitrophenyl esters of *o*-iodobenzoic, *p*-iodobenzoic, and 3,4,5-triiodobenzoic acid, which were prepared according to methods described by O'Donnell *et al.*<sup>12</sup> and by Zahn and Schade<sup>13</sup>. Degreased mohair was washed twice with a non-ionic detergent in a buffered solution of pH 5.04 (sodium acetate and acetic acid) at 40° C, and 0.3 g of dry fibres were allowed to react at 40° C with a solution of 0.15 g of ester or a saturated solution of the ester in 25 ml. of dimethylsulphoxide, with gentle stirring, for 15–24 h. The solution was later sucked off and the specimen was washed twice with dimethylsulphoxide followed by ether extraction and isoionic washing.

A partial iodination of mohair, carried out by the method of Richards and Speakman<sup>6</sup>, ensured complete dehydration. This was carried out because the tyrosine content of mohair is, especially in the  $\alpha$ -keratose component, smaller than in wool<sup>14</sup> and in order to see whether the fine structure remains unchanged after iodination treatment. The dry fibres were soaked for 8 days at 25° C in a saturated solution of iodine in absolute ethanol, and excess iodine was removed and the sample was washed isoionically.

The lysine and tyrosine content of mohair, determined by automatic amino-acid analysis, is 249 and 254  $\mu$ moles/g, respectively. A determination of the free side-chains of histidine, serine, cysteine, lysine and tyrosine by the dinitrophenyl technique<sup>15</sup> shows that nearly all of the lysine side-chains of the differently treated samples are acylated by the iodinated benzoic acids, whereas the concentrations of the other free side-chains remain unchanged within the accuracy of the dinitrophenyl analysis. The iodine contents were determined by quantitative elementary analysis and are summarized in Table 1. The labelled lysine of samples I to III was calculated, assuming that the *p*-nitrophenyl esters had reacted with the lysine side-chains only. The calculated quantity of labelled lysine of sample III shows, however, that some of the iodobenzoyl groups may be differently incorporated.

The low-angle X-ray diffraction patterns were obtained on films with nickel-filtered copper K $\alpha$ -radiation in an evacuated Kiessig-type camera<sup>16</sup>. The collimating system of a commercial pinhole camera was modified so that the patterns were absolutely free of pinhole scattering down to Bragg-angles equalling about 100 Å. Molybdenum disulphide powder was used as an internal standard (6.15 Å).

The pattern of the untreated mohair samples shows a series of sharp meridional and near meridional reflexions (Figs. 1a and 2). In comparison with this fibre diagram there is a relative intensification and broadening of the 39 Å-meridional reflexion in the fibre pattern of a mohair sample stained with triiodobenzoyl groups (Figs. 1b and 2). The same effect, although to a smaller extent, is observed in the patterns of the samples I and II, the lysine  $\epsilon$ -amino groups of which are acylated with monoiodobenzoic acids.

Table 1. IODINE CONTENT OF THE DIFFERENTLY TREATED MOHAIR SAMPLES AND ITS CALCULATED AMOUNTS OF LABELLED LYSINE OR TYROSINE

Sample	Treatment	Weight of iodine (per cent)	Amino-acid which reacted, calculated from the iodine content ( $\mu$ moles/g)
I	<i>o</i> -iodobenzoic acid ester	2.15	176 lysine
II	<i>p</i> -iodobenzoic acid ester	2.66	220 lysine
III	3,4,5-triiodobenzoic acid ester	10.53	309 lysine
IV	Iodination in ethanol	1.65	66 tyrosine*

\* Calculated assuming that iodine reacts only with tyrosine yielding 3,5-diiodotyrosine.

Fig. 1. X-ray patterns of fibres of mohair (axis of fibre vertical). *a*, Untreated; *b*, stained with triiodobenzoyl groups.

Fig. 2. Curves of X-ray patterns of fibres measured with a meridional photometer. *a*, Untreated mohair; *b*, mohair stained with triiodobenzoyl groups.

Lysine residues, therefore, seem to have an axial periodicity of 39 Å. The reason for the broad extension of this reflexion on its layer line is a statistical distribution of the strong scattering triiodobenzoylic residues which are situated relatively far from the polypeptide backbone. The rather less meridional broadening of this reflexion may have the same cause, but this unequal broadening can be explained by a statistical mobility of the amino-acid side-chains in the axial and lateral direction, which is probably different.

The 66 Å-reflexion is also intensified, and remains the prominent reflexion on the meridian. This is observed also in the patterns of partial iodinated mohair as well as of mohair which has reacted with unlabelled *p*-nitrophenyl esters. This effect, therefore, could depend on an axial repetition of structural sub-units which are more ordered after chemical treatment in a medium which causes swelling. This interpretation seems probable if it is remembered that cysting is located in this axial periodicity<sup>7</sup>, which could be confirmed in the case of mohair, and if it is accepted that the protofibrils are cross-linked with the matrix by cystine.

The fibre pattern of a mohair sample, the tyrosine residues of which are partially iodinated (sample IV), shows no alteration of the basic structure, but besides the well known intensification of the sixth order of the 198 Å repeat at 33 Å there is a somewhat smaller intensification of the ninth order at 22 Å. Contrary to the "lysine reflexion" at 39 Å, the "tyrosine reflexion" at 33 Å is not essentially broadened. This observation supports the

concept that the feature of intensified meridional reflexions depends on the geometry of the incorporated labelled residues. In this connexion it must be remembered that the results of our chemical variations are quasi-isomorphous replacements only.

All diagrams of fibres of mohair show discrete equatorial reflexions at 80 Å, 42 Å, 27 Å and 9.3 Å. The 27 Å reflexion, however, is intensified in patterns of the samples with the lysine content stained. We consider that the lysine residues are distributed on the periphery of the protofibrils. On the other hand, the 42 Å reflexions and the 27 Å reflexions are intensified in the pattern of the samples with lysine stained. If the 42 Å equatorial reflexion corresponds to the order of microfibrillar packing the tyrosine residues are situated on the periphery of the protofibrils as well. The lateral arrangement of the microfibrils is more ordered in the sample stained in the tyrosine (IV) than in the samples stained in the lysine and treated at elevated temperatures.

We have shown that specific staining of lysine is possible. We found an axial periodicity of lysine residues in the structural units of mohair and a distribution of these residues on the periphery of the protofibrils. Results could be reproduced for Lincoln wool but will be discussed elsewhere.

We thank Prof. Dr.-Ing. H. Zahn for his interest, Dr. K. Ziegler for amino-acid analysis, Miss A. Augenadel and Miss K. Prickartz for technical assistance. This research was supported in part by a grant from the U.S. Department of Agriculture. The mohair was provided by the Mohair Board of South Africa.

## BIOPHYSICS

### Enzyme Activity in High Magnetic Fields

THE change of the catalytic enzyme activity under the influence of an external magnetic field was demonstrated for carboxydismutase<sup>1</sup>, for glutamate dehydrogenase<sup>2</sup> and for trypsin<sup>3</sup>. Dorfman<sup>4</sup> was the first to predict these magneto-catalytic effects and more recent theoretical discussions are due to Neurath<sup>5</sup>, Valentinuzzi<sup>6</sup> and Gross<sup>7</sup>. The following summary is based on Dorfman's work.

In a non-uniform magnetic field the force acting on a large molecule in solution tends to produce a concentration gradient. The distribution of diamagnetic macromolecules as a function of the distance  $x$  from the point of highest

magnetic field is given by Boltzmann's law  $dN = \text{constant} \exp(-\alpha x dx)$  with  $\alpha = \frac{M\chi_m H dH/dx}{2RT}$ . Here  $\chi$  is the diamagnetic susceptibility/g ( $\sim 10^{-6}$ ),  $M$  the molecular weight of the macromolecule and  $H$  the magnetic field. With  $H = 10^5$  G,  $dH/dx = 10^4$  G cm $^{-1}$  and  $M = 250,000$ , one finds that  $\alpha = 0.005$ , that is, the concentration is practically uniform. For macromolecules of larger molecular weights one can expect noticeable concentration gradients which could influence the velocity of enzyme reactions.

Effects in a uniform field could occur for magnetically anisotropic macromolecules, for example, fibrous protein molecules or nucleic acids made up of anisotropic building blocks. The magnetic field tends to align the molecules; the degree of orientation, or departure from an isotropic distribution of the axes of the molecules, is determined by the Boltzmann factor  $\exp(-\Delta\chi_m H^2/2RT)$ , where  $\Delta\chi_m$  is the anisotropy of the molar susceptibility. Here again the calculation shows that for strongly anisotropic diamagnetic macromolecules of molecular weights of the order of  $10^6$  the degree of alignment should be almost complete in fields of  $\sim 10^5$  G.

Earlier measurements<sup>1</sup> were carried out in a magnetic field of 15 kG. These have now been extended to 80 kG with the help of the high field facilities of the Clarendon Laboratory, Oxford. One of the standard watercooled solenoids of 5 cm inner diameter was used for these experiments.

For the study of the magnetocatalytic effect in L-glutamic dehydrogenase (GDH) the following reaction catalysed by GDH was used:

The enzyme activity is expressed in enzyme-units (E). This is defined as the amount of enzyme which, when dissolved in 1 ml, produces in 100 sec a change of 0.100 in the extinction of light of 3660 Å by a 1 cm layer of reduced nicotinamide-adenine dinucleotide (NADH), at a temperature of 25°C. In the experimental procedure 3 ml. of 0.05 molar triethanolamine buffer (pH = 8.0), 0.045 ml. of 0.01 molar ethylenediaminetetraacetate solution, and amounts ranging between 0.02 and 0.1 ml. of a solution of GDH (about  $10^{-7}$  moles/l.) were introduced into an absorption cell of 1 cm thickness. After adding 0.06 ml. of 0.4 molar Na 2-oxoglutarate solution the extinction was measured at 1–2 min intervals for a period of 5–10 min. The cell was then placed in the field for periods of 17–60 min and after removal from the field the rate of change of the extinction was measured again. Control measurements in zero magnetic field were done simultaneously on another identical sample kept as far as possible at the same temperature. The importance of good temperature control and the need to correct for small temperature variations have already been emphasized<sup>1</sup>.

In the case of catalase the influence of the magnetic field on the activity was determined by the catalytic decomposition of hydrogen peroxide. The catalytic activity is defined as  $\text{Cat.f} = k/c$  (ref. 8), where  $k$  is the reaction velocity constant of the decomposition of hydrogen peroxide (in min $^{-1}$ ) and  $c$  the concentration of the enzyme solution in g/50 ml. The method of Warburg and Krippahl<sup>9</sup> was used to determine  $k$ : the reaction was stopped after a given time by the addition of hydrocyanic acid and the remaining hydrogen peroxide determined spectrophotometrically with vanadic acid.

The experiments were carried out both in a uniform magnetic field (variation of 3 per cent over the sample length of 4 cm) and in a non-uniform field (variation of 30 per cent over 4 cm).

The results for GDH are given in Table 1. The last column shows that, while in a uniform field the decrease in activity fluctuates between about 5 per cent and 12 per

	0	22.2		5.10		

cent, in a non-uniform field it reaches very high values. The fact that, as shown by runs Nos. 5, 6 and 8, it is possible to bring the reaction almost to a standstill reversibly by a physical method may lead to the development of new techniques for the study of enzyme reactions.

Table 2 lists the results for catalase. In contrast to the measurements by Haberditzl and Muller in 15 kG (ref. 1), which showed no effect, the present experiments indicate appreciable increases in the activity with field, especially for non-uniform fields.

A detailed discussion of these results will follow later. It may be mentioned, however, that in the case of catalase the unexpected increase in activity with field could be explained by a secondary effect, namely, the accelerated removal of the paramagnetic oxygen from the site of the reaction.

I thank Dr. N. Kurti for his encouragement and interest, Professor Sir Hans Krebs and Professor Otto Warburg for providing the enzyme preparations, and Mr. J. Good, Mr. P. Hudson and Dr. P. F. D. Shaw for their help in the various phases of the experiments.

This work was carried out in the Clarendon Laboratory (Mullard Cryomagnetic Laboratory), Oxford.

## Nuclear Magnetic Resonance Spectroscopic Studies of Erythrocyte Membranes

THE nature of molecular interactions in the lipoprotein complexes of biological membranes has been a subject under active enquiry for many years. The classical Davson-Danielli paucimolecular model<sup>1</sup> postulates apolar mutual interaction between the lipid molecules and electrostatic binding of the lipid with the structural protein. Although this model has received support from biophysical studies, especially on myelin<sup>2,3</sup>, there is other experimental evidence which suggests that extensive hydrophobic binding may occur between lipids and proteins, for example, from studies on mitochondria<sup>4,5</sup>, halobacterium halobium<sup>6</sup>, erythrocyte ghosts<sup>7</sup>, plasma membrane fragments of Ehrlich ascites cells (D. F. H. Wallach and P. H. Zahler, personal communication) and chloroplast lamellae<sup>8</sup>.

A number of physical methods have now been used to study the structure of membranes. These include polarization microscopy, electron microscopy, X-ray diffraction, infra-red spectroscopy, ultra-violet optical rotatory dispersion and fluorescence emission spectroscopy. These methods have yielded valuable information regarding membrane thickness, fine structure of lipoprotein layers and conformational states of structural protein of the membrane. Little or no work has been reported on membranes utilizing nuclear magnetic resonance spectroscopy. In a previous communication, Chapman and Penkett<sup>9</sup> demonstrated the usefulness of nuclear magnetic resonance to investigate the interaction of phospholipids such as egg yolk lecithin with cholesterol. In order to examine the feasibility of using high resolution nuclear magnetic resonance spectroscopy as a structural probe for lipoprotein systems, this type of study is now being extended directly to a study of natural membrane systems. Preliminary results obtained with erythrocyte membranes using this spectroscopic technique are reported in this communication.

Haemoglobin-free ghosts were prepared in essential accordance with the method of Dodge *et al.*<sup>10</sup> from 2 week old human erythrocytes preserved in acid-citrate dextrose at 0°–4° C. For nuclear magnetic resonance study, the membrane material was treated as follows. (a) Freshly prepared ghosts derived from 3–5 c.c. packed erythrocytes were equilibrated by ultracentrifugation with deuterated 20 milliosmolar phosphate buffer pH 7.4, and resuspended in 1 ml. of the deuterated buffer. (b) Washed ghosts were desalted by dialysis against distilled and deionized water and freeze-dried. Between thirty and fifty milligrams of dried material was suspended in 1 ml. of either deuterated 20 milliosmolar phosphate buffer pH 7.4 or in deuterium oxide (99.7 per cent) alone. (c) 30–50 mg dried material was suspended in 1 ml. of 1 per cent sodium deoxycholate in 99.7 per cent deuterium oxide.

These materials were examined either as suspensions or as dispersions formed by ultrasonic irradiation. High resolution nuclear magnetic resonance spectra were obtained with a computer averaging technique attachment in a spectrometer at 34° C.

Fig. 1a shows the spectrum of freeze-dried membrane material resuspended in deuterated phosphate buffer pH 7.4. An identical spectrum was obtained with either freshly prepared ghosts in deuterated buffer or freeze-dried material in unbuffered deuterium oxide, and with or without sonication. The reproducibility of this spectrum was checked on three different preparations.

The high resolution signals are expected to originate as a result of the molecular motion of non-protein moieties in the membrane. This is because proteins in general have been shown not to give well defined nuclear magnetic resonance signals<sup>11</sup>.

The spectrum shows distinct signals which we assign to the probable functional groups corresponding to  $N^+(CH_3)_3$  groups of choline at 6.7  $\tau$  and  $N$ -acetyl groups at

7.88  $\tau$  from sialic acid. Sialic acid is considered to be a principal charge determinant of the erythrocyte membrane surface<sup>12</sup>. The identity of the latter signal was tentatively decided after examination of the nuclear resonance spectrum of pure sialic acid. It can be seen that the signals in the region which are characteristic of protons in the  $(CH_2)_n$  groups of alkyl chains near 8.8  $\tau$  are low and not discernible. A possible explanation for this could be that the hydrocarbon chains are restricted in their mobility because of the presence of hydrophobic interaction between sterol and lipid and/or lipid and protein. The sharpness of the signal at 6.65 p.p.m. indicates, however, that at least some of the methyl protons of the choline groups of the membrane lipids are free to move.

Sodium deoxycholate is widely used to solubilize biological membranes and so we have examined the nuclear magnetic resonance spectrum of a membrane treated with this material. The spectrum of freeze-dried material in 1 per cent sodium deoxycholate is shown in Fig. 1b (the nuclear magnetic resonance spectrum of sodium deoxycholate alone is shown as a dotted line). The membrane spectrum shows a fairly narrow signal near 8.8 p.p.m. which we associate with the protons of the hydrocarbon chains of the lipid material. The chains of the lipid apparently have more freedom to move as a result of the treatment. The detailed mechanism by which the deoxycholate brings about this change is uncertain. It is possible that it reduces hydrophobic interaction between the lipid and sterol or lipid and protein in the membrane. The modification of the nuclear resonance signals which arises from sodium deoxycholate in the presence of the membrane may be caused by the formation of a complex.

We have now obtained many other nuclear magnetic resonance spectra of membranes treated in various ways and are continuing to investigate in more detail the

## BIOCHEMISTRY

### Characteristics of Adult and Foetal Myoglobin in the Visible Light Spectrum

A MYOGLOBIN which differed from adult myoglobin (MbA) was found in the urine<sup>1</sup> of a 28-year-old woman during an episode of idiopathic rhabdomyolysis with myoglobinuria. The same haem protein was later demonstrated in the patient's skeletal muscle<sup>2</sup> where it comprised the bulk of the benzidine positive protein after haemoglobin and cytochrome *c* had been separated from the myoglobin by column chromatography. This distinct chromoprotein was similar in its solubility in ammonium sulphate, spectroscopic characteristics and on cellulose acetate electrophoresis to foetal skeletal myoglobin (MbF) prepared in the same manner from the psoas muscle of infants stillborn at term. It was concluded that myoglobin, like haemoglobin, can present molecular variations which express themselves as disease syndromes, for example, rhabdomyolysis, under certain conditions. Although these clinical and biochemical findings have been supported by one investigator<sup>3</sup>, other reports do not regard MbF as an entity but rather as an artefact produced by the method used in preparing the myoglobin for analysis. The evidence against MbF has recently been summarized<sup>4</sup>. The present report examines the spectroscopic characteristics of MbA and MbF, adult and foetal haemoglobin (HbA and HbF, respectively) derived from muscle and blood of the human, dog and pig. The methods were designed to study the various pigments under optimum and standard conditions to minimize the effects of changing pH, salt concentrations, temperature, state of haem oxidation, crystallizations and other manipulations.

Cardiac and skeletal muscle was obtained fresh from adult and newly born dogs and pigs. The samples were quickly frozen and then ground in a meat grinder, titrated with small portions of cold distilled water and spun at 9,000g for 30 min to remove the particulate matter. Instead of grinding them before centrifugation, some of the samples were homogenized in a blender. The supernatant muscle liquor was then treated in one of two ways—either immediately freeze-dried for later analysis or added directly in 1–2 ml. amounts to a 2.5- by 30-cm 'Sephadex G-50' fine (200–400 mesh) gel column<sup>5</sup> which was developed in 0.05 molar phosphate buffer (pH 7.40)

with 0.05 molar sodium chloride. The spectroscopic results were the same regardless of the method at this step, that is, either freeze drying first or direct application to the 'Sephadex' column. The oxy forms were slowly converted, however, to the corresponding met compound in the freeze-dried state. Animal HbA and HbF were obtained from appropriate heparinized whole blood samples by aspirating the plasma and buffy coat and washing the residual cells three times with isotonic saline. The red cells were then haemolysed with two volumes of distilled water and the ghosts and other particles removed by centrifugation and filtration through acid-washed glass wool. The red cell liquor was applied to the 'Sephadex' column in 0.5–1.0 ml. amounts and similarly eluted with the developing solution. The total time taken for the elution was less than 2 h. Human muscle samples—both adult and foetal—were obtained *post mortem* and were treated in the same manner. Human HbA was prepared fresh from the blood of normal adult volunteers whereas HbF was prepared from foetal cord blood of healthy newborn infants. The 'Sephadex' column effectively separated myoglobin and haemoglobin either from the muscle homogenates or when haemoglobin and myoglobin were deliberately mixed together. All isolation procedures were carried out at 6° C and a Carey 15 automatic recording spectrophotometer was used for the final spectral readings. It should be noted that there were no differences in the rates of migration in the columns or effective separation when the eluted samples were applied directly to CMC columns<sup>6</sup>. The muscle homogenates of all adult species, including both skeletal and heart muscle, clearly separated on the 'Sephadex' column into a "fast" moving haemoglobin and a slower myoglobin band. Foetal muscle liquor, except that made from the heart muscle, was characteristically very opalescent and less coloured than the adult liquor or the haemoglobin preparations. This contributed to the high background in the visible light spectrum characteristic of skeletal MbF. Attempts to remove the opalescent colloidal-like background from the visible pigment by the use of 'Millipore' filters of graded pore size and centrifugal separation were not successful. It was thought that the opalescent quality was inherent to and characteristic of the foetal haem pigment. When the foetal skeletal muscle supernate was applied to the columns it yielded only a single band similar in this respect to the haemoglobins. The foetal pigment tended to show more column spread, although it remained homogeneously pink and opalescent in the oxy form. Two bands were formed on the column when MbF from pig heart was applied, but the distinction was not always present when MbF from human hearts was similarly chromatographed.

Table 1. SPECTROPHOTOMETRIC MAXIMA\* OF ADULT AND FOETAL HAEM PROTEINS

	Source	Oxy		Met-nitrite		Reduction-dithionite	
		$\alpha$	$\beta$				
Adult and foetal haemoglobin	Human	576	540	540	630	576	544
	Dog	577	540	542	630	578	540
	Pig	576	540	540	628	574	542
Adult myoglobin from skeletal muscle	Human	583	545	502	630	585	543
	Dog	582	543	500	628	583	544
	Pig	582	543	504	632	584	543
Foetal myoglobin from skeletal muscle	Human	578	540	540	630	578	542
	Dog	578	541	538	628	576	541
	Pig	577	540	538	630	577	542

\* Each sample was adjusted in the oxy form to read 0.200 optical density units at 580 m $\mu$ .

The results of all the spectroscopic maxima for the skeletal muscle are summarized in Table 1. Oxy HbA and HbF had the same maxima ( $\alpha$  576 m $\mu$  and  $\beta$  540 m $\mu$ ) and no species differences were noted. Oxy MbA had maxima at 583 m $\mu$  and 543 m $\mu$ . The spectrum of oxy MbF from skeletal muscle resembled that of oxy HbA and F in the human, dog and pig. In contrast, foetal heart muscle myoglobin from the pig had the same column separation pattern as the adult skeletal and heart muscle preparations and spectroscopically the second or slower

elution band had the characteristic peaks of MbA in the oxy form. As indicated, this finding was less consistent in the human foetal heart. Some specimens behaved exactly as those described for the foetal pig and others failed to separate into the two moieties. In the latter instance the single band had a spectral pattern indistinguishable from the haemoglobins in the oxy form. Conversion of the myoglobin liquors and the haemoglobins to the corresponding met forms by oxidation with small constant amounts of crystalline sodium nitrite yielded a maximum at 500 m $\mu$  only with MbA and maxima of 630 m $\mu$  for MbA, MbF, HbA and HbF in all species regardless of whether the muscle was cardiac or skeletal. The haemoglobins retained minimal peaks at 540 and occasionally a small peak at 576 m $\mu$  and these maxima were more resistant to met conversion than the  $\alpha$  and  $\beta$  peaks of MbA which completely disappeared. Thus only MbA exhibited a characteristic plateau between 560 m $\mu$  and 610 m $\mu$  (Fig. 1). Foetal skeletal muscle myoglobin resembled HbA and HbF in both the oxy and met forms, and thus the only distinct spectroscopic pattern was that of MbA. Foetal cardiac Mb, when indistinguishable from MbA (see above), was not different in the oxy spectral maxima but always differed in the met type by not developing either the 560–610 m $\mu$  plateau or the maximum at 500 m $\mu$ . Reduction with dithionite ( $\text{Na}_2\text{S}_2\text{O}_4$ ) of either auto-oxidized or sodium nitrite oxidized haemoglobin or myoglobin of each type and from each species returned the met spectra toward their previous oxy pattern. This proved to be a valuable analytical tool enabling the  $\alpha$  and  $\beta$  maxima to be analysed to identify properly the origin of the haem protein. The spectra of met HbA and F and skeletal muscle MbF after reduction with dithionite returned to about 576 m $\mu$  and 542 m $\mu$ , and MbA and cardiac myoglobin from the foetuses to 580 m $\mu$  and 545 m $\mu$ . Exceptions were noted with regard to the cardiac myoglobin derived from foetal human hearts where the oxy pattern was initially indistinguishable from that of the haemoglobins. Dithionite in this instance also returned the spectroscopic peaks to their original pattern. The contour of peaks after chemical reduction was somewhat less sharp in terms of the maxima; however, the  $\alpha$  peak clearly distinguished adult myoglobin from the haemoglobins and foetal skeletal myoglobin. The 630 m $\mu$  peak after conversion of either myoglobins or haemoglobins also disappeared after dithionite reduction. The Soret bands were not significantly different between haem protein types either in the oxy or met state or after dithionite reduction. Cytochrome *c* and catalase which have molecular weights similar to myoglobin could potentially on the basis of column separation alone interfere with the spectral analyses.

Fig. 1. Spectroscopic maxima of neutral (pH 7.4) haem proteins. The wavelengths in m $\mu$  are indicated on the abscissa and the optical density on the ordinate. —, Foetal methaemoglobin; ---, foetal met-myoglobin; - · - ·, adult met-myoglobin.

Under the conditions described, however, ferro- and ferri-cytochrome *c* have maxima at 550 m $\mu$  and 522 m $\mu$ , and 565 m $\mu$  and 530 m $\mu$ , respectively, while catalase at the neutral pH has a characteristic maximum at 624 m $\mu$ . In addition, dithionite reduction produces maxima for catalase at 594 m $\mu$  and 596 m $\mu$ . These peaks were not observed in our experiments.

These observations emphasize a further difference between MbA and MbF in skeletal muscle and support the impression<sup>2,7</sup> that MbF more closely resembles the haemoglobins than it does MbA. That MbF derived from cardiac muscle behaved in some experiments like MbA may indicate that the characteristics of adult myoglobin evolve first in heart muscle which more closely approximates the functional or physical activities of adult skeletal muscle *in utero* than does foetal skeletal muscle. The spectral evolution of oxy MbF begins in the  $\alpha$  and  $\beta$  peaks with the slight shift of the maxima toward the longer wavelengths. The last characteristics of MbA to appear are found in the met state with an increase in light transmittance between 5600 and 6100 Å and the appearance of the peak at 5000 Å. These changes are coincident with the progressive decrease in the quantity of rapidly migrating haem protein on electrophoresis<sup>1-3</sup>.

### Reversible Inactivation of *Helix (pomatia)* Agglutinin by 2-Mercapto-ethanol

THAT certain snails contain an agglutinin with human anti-A specificity was first observed by Prokop *et al.*<sup>1</sup> and then independently by Boyd and Brown<sup>2</sup>. Since then, however, we have discovered that this agglutinin (which can be obtained from the protein gland of the sexual organ of *Helix pomatia*) also reacts with human O and B cells treated with neuraminidase, with the respective erythrocyte mucoids, and with many animal cells, especially after treatment with proteolytic enzymes or neuraminidase<sup>3</sup>. We have also found that some glycoproteins and glycolipids react with this agglutinin<sup>4</sup>, and have come to the conclusion that for the reaction with the *Helix* agglutinin only the presence of terminal non-reducing bound *N*-acetyl-D-galactosamine, often blocked by neuraminic acid, is necessary irrespective of whether it is in  $\alpha$ - or  $\beta$ -linkage.

In order to obtain further information on the nature of this agglutinin, we treated it with 2-mercapto-ethanol (1 molar, 0.5 molar and 0.1 molar) at room temperature. This procedure led to a complete inactivation of the agglutination power, even when the clumped cells were exposed to this reducing agent. Dialysis or standing the test-tubes overnight resulted in a restoration of the agglutinating power, obviously as a result of re-oxidation. These experiments suggest that the structures (shown in Fig. 1a and b) may be taken into consideration for the

Fig. 1. Proposed structural models for the agglutinin from *Helix pomatia*. Protein chain(s).

*Helix* agglutinin, provided that the mode of action of 2-mercapto-ethanol causes a reversible reduction of the disulphide bonds which are involved in building up the combining site of the agglutinin.

By "reversed" immunoelectrophoresis using secreted A substance and neuraminidase-treated human erythrocyte mucoids as indicator, we were able to demonstrate the presence of *Helix* agglutinin in the region of the gamma-globulins. It is possible, therefore, that it plays some part in establishing an "immune" barrier towards the micro-organism; moreover, we have seen bacterial agglutination by this agglutinin. Preliminary experiments have revealed that the *Helix* agglutinin is remarkably resistant towards the destructive action of proteolytic enzymes.

### Restoration of Enzyme Activity of Heat-denatured Acetylcholinesterase by Antibodies to the Native Enzyme

THE enzyme acetylcholinesterase (AChE), which catalyses the hydrolysis of acetylcholine to choline and acetic acid, has been the subject of a great deal of interest not only in connexion with its structure and mode of action but also because of the role usually attributed to acetylcholine in the transmission of nerve stimuli<sup>1</sup>. We have carried out experiments to investigate the effect of heat on the activity and antigenic properties of this enzyme, and these have revealed that the activity of the enzyme can be restored after heat denaturation by adding antibodies to the native enzyme. What follows is a report on these experiments.

A stock solution of 20 mg/ml. bovine red blood cell AChE preparation was made up in *tris*-buffered saline (0.01 molar *tris* buffer pH 7.9 containing 0.15 molar sodium chloride). Tubes containing 0.70 ml. of *tris*-buffered saline were heated to the desired temperatures in a thermo-

statically controlled water bath equipped with a shaker; 0.05 ml. of the enzyme stock solution was then added to each tube. 0.05 ml. portions were withdrawn at intervals from each tube and assayed for activity according to the colorimetric method of Ellman *et al.*<sup>2</sup>. Reaction rates were obtained by spectrophotometry at 412 mμ for 5 min, at 1 min intervals; results are expressed in terms either of optical density units per hour, or the same units per min. Fig. 1 shows that the critical denaturation temperature for this enzyme preparation is 58° C. Heating at temperatures below 58° C over a period of 10 min caused a gradual loss of enzyme activity, but heating at 59° C and at 60° C for only 3–5 min resulted in a sharp decline in enzyme activity.

Fig. 1. Effect of heat on the enzyme activity of AChE.

In order to investigate the effect of antibodies to acetylcholinesterase\* on the denatured enzyme, 0.05 ml. portions of stock AChE solution were added to 0.70 ml. *tris*-buffered saline at 60° C in a water bath. Each tube was then heated for a specified time as indicated in Table 1, removed from the water bath and allowed to cool to room temperature. After cooling, 0.5 ml. portions of *tris*-buffered saline containing anti-AChE globulins (derived from 0.5 ml. antiserum) were added to each tube. The tubes were left overnight in the cold and the immune precipitates were removed by centrifugation. The precipitates were washed twice with *tris*-buffered saline and were suspended in 1.25 ml. of *tris*-buffered saline. 0.05 ml. portions of the precipitates and supernatants were assayed for AChE activity.

The results are given in Table 1. They show that virtually all enzyme activity (99–100 per cent) was destroyed when the enzyme was heated at 60° C for the given periods. On addition of anti-AChE globulins to the denatured enzyme, however, about 7.5 per cent of the initial activity was found in the supernatant. No significant activity could be detected in the immune precipitate. The results in Table 1 further show that antibody to native AChE is essential for the renaturation of heat denatured AChE; without addition of the anti-AChE globulins or on the addition of control globulins, the denatured enzyme failed to regain activity within a period of 24 h.

The appearance of enzyme activity in the supernatant after addition of anti-AChE globulins to denatured

\* The antibodies were obtained by repeated intramuscular injections of rabbits with 10 mg of the AChE preparation in 1 ml. saline emulsified with an equal volume of Freund's complete adjuvant. Anti-AChE globulins and control globulins were prepared by three precipitations of sera at 33 per cent saturation of ammonium sulphate. These globulin preparations lacked esterase activity.

Table 1. EFFECT OF ANTI-ACETYLCHOLINESTERASE GLOBULINS ON HEAT DENATURED ENZYME

Preparation	Time of heating at 60° C (min)	Enzyme activity* after heating	Enzyme activity* on addition of globulins Anti-acetylcholinesterase Activity in supernatant precipitate	Control globulins Total activity
AChE in tris-buffered saline, pH 7.9	0	19.740	11.844

	45	0.000	0.045	
	60	0.000	0.045	
	5†	0.234	1.485	
	60	0.000	1.500	0.000
Tris-buffered saline, pH 7.9	0	0.000		

\* Optical density per hour (at 412 mμ).

† Antibodies were added after storage at 4° C for 18 h.

AChE indicates the possibility that as a result of the interaction between the denatured enzyme and antibodies to the native AChE, a partial renaturation of the enzyme occurred. The presence of a soluble complex resulting from this interaction was shown by adding goat anti-rabbit serum to the supernatant described in Table 1. This resulted in the quantitative precipitation of the renatured enzyme.

We attempted to investigate the kinetics of the renaturation process by assaying the restoration of enzyme activity at different intervals after the addition of anti-AChE globulins. The results are summarized in Table 2. Table 2 clearly indicates that the renaturation process is complete within 1 min of addition of antibody. Essentially the same amount of activity was restored when antibodies were added either immediately or 24 h after heat treatment of the enzyme.

Table 2. TIME INVESTIGATIONS ON THE RENATURATION OF ACETYLCHOLINESTERASE FOLLOWING ADDITION OF ANTI-ACETYLCHOLINESTERASE GLOBULINS

Time of addition of globulins after heating	Time interval between addition of globulins and assay of enzyme activity	Enzyme activity*
Immediate	1 min	1.560
	15 min	1.650
	30 min	1.620
	90 min	1.635
	18 h	1.575
24 h	1 min	1.515

\* Optical density per hour (at 412 mμ).

The mechanism by which the enzyme activity of heat denatured enzyme is restored by antibodies to the native enzyme preparation is still unknown. The combination of antigen antibody may have resulted in a partial refolding of the denatured enzyme sufficient to restore part of its enzyme activity. It is also possible that the formation of the enzyme antibody complex may have resulted in the contribution of a structural component by the antibody, necessary for the catalytic activity of the enzyme. These possibilities are at present under investigation.

## Inhibition of Glutamic Dehydrogenase by Clomiphene

GLUTAMIC dehydrogenase (GDH) has been used as a model enzyme in the study of the interaction between steroid hormones and enzymes<sup>1</sup>. It was found that in experiments *in vitro* 17β-oestradiol, oestriol, oestrone and diethylstilboestrol (DES) inhibited the action of GDH, DES being the strongest inhibitor. During the past few years, clomiphene, that is, 1-[p-(β-diethylaminoethoxy)-phenyl]-1,2-diphenyl-2-chloroethylene,

Clomiphene

has been applied to induce ovulation in anovulatory patients<sup>2</sup>, although the mechanism of its action is not yet fully understood. Comparison of the structures of DES (that is, α,α'-diethylenstilbestenediol)

DES

and clomiphene reveals some similarities: both compounds are derivatives of ethylene and both contain at least two phenyl groups.

GDH catalyses the reaction: α-ketoglutarate + ammonium ion (NH<sub>4</sub><sup>+</sup>) + reduced nicotinamide-adenine dinucleotide (NADH) ⇌ L(+)-glutamate + nicotinamide-adenine dinucleotide (NAD) + water. The reaction can be studied by determining the decrease of extinction at 366 nm, caused by the oxidation of NADH (ref. 3).

The activity of GDH and the degree of inhibition were measured by the "Boehringer GLDH test". The inhibitors (clomiphene as citrate and DES) were dissolved in a 1 : 1 mixture of propylene glycol and water.

The results are shown in Fig. 1. For comparison, the experiment of Yielding and Tomkins<sup>1</sup> with DES was repeated. We found in our experiments that DES caused a 50 per cent inhibition at a concentration of 2 × 10<sup>-6</sup> mole/l., which is in agreement with previous results<sup>1</sup>. Clomiphene caused the same inhibition at about the same concentration, 1.9 × 10<sup>-6</sup> mole/l. The maximum amount of inhibition (about 65 per cent) by clomiphene was at a concentration of 4 × 10<sup>-6</sup> mole/l.; at the same concentration, DES caused an inhibition of 85 per cent.

Fig. 1. Effect of DES and clomiphene on the GDH reaction.

Yielding and Tomkins<sup>1</sup> suggested that the inhibition of the GDH activity by steroids might be caused by the splitting of the GDH molecule into smaller units, while Hofmann<sup>4</sup> has directed attention to the aromatic character of steroids which are  $\pi$  shell compounds. In this connexion, we note that only DES—the most powerful inhibitor—and clomiphene have as a common part in their structure a  $—C=C—$  bond. It represents a special type of reactive  $\pi$  electron bond. This might be the key point of the inhibiting property of these two compounds. Being very reactive, this bond may attack the hydrophobic points of GDH molecule and so split it into smaller units which has been suggested to be the cause of inactivation<sup>1</sup>.

We thank Messrs. Star, Tampere, Finland, for their gift of clomiphene citrate.

### Nucleotide Pyrophosphatase of *Tetrahymena pyriformis*

IN an investigation of the synthesis of nicotinamide adenine dinucleotide (NAD) by *Tetrahymena pyriformis* we examined the enzyme cleavage of NAD by this ciliate. There seems to be a lack of information about the cleavage of this coenzyme by Protozoa<sup>1,2</sup>. In preliminary experiments we incubated cell-free homogenates with NAD and saw that its activity, measured with alcohol dehydrogenase, disappeared rapidly, and detailed investigation to identify the enzyme responsible for the cleavage of NAD seemed to be necessary.

In the case of NADase, nicotinamide is liberated and the complex with cyanide is lost<sup>1</sup>. When the cleavage is in the pyrophosphate bond, the activity of the coenzyme is destroyed, but the capacity to form a complex with cyanide is maintained. NADase is also inhibited by nicotinamide, while pyrophosphatase is not. Phosphorus is released as in the case of sweet almonds and intestinal pyrophosphatases<sup>3</sup>.

*Tetrahymena pyriformis*, variety I, mating type II, cultured in 2 per cent peptone 'Difco' and 0.5 per cent glucose, was used for these experiments. In some cases, 0.1 per cent 'Difco' yeast extract was also added to the medium. After 3 days of incubation at 25° C, without shaking, the cells were collected and washed with distilled water and centrifuged at 2,000 r.p.m.

The cells were suspended in 0.02 molar phosphate buffer, pH 7.0, and submitted to ultrasonic treatment in an MSE apparatus for 3 min in an ice bath (until no intact cells could be detected microscopically). The sonicate was centrifuged at 6,000g and 4° C and the supernatant was used in the experiments. Coenzyme activity of the extracts prepared with 0.02 molar phosphate buffer, pH 7.0, was determined with alcohol dehydrogenase<sup>4</sup>. Crystalline alcohol dehydrogenase diluted to contain 500 u/ml. and NAD (97.5 per cent pure) were used. Phosphorus was estimated by Fiske and Subbarow's method modified by Gomori<sup>5</sup> and proteins by the method of Warburg and Christian, using the formula of Kalkar<sup>6</sup>. The cyanide complex was measured according to Colowick, Ciotti and Kaplan<sup>4</sup>. The extracts for phosphorus were prepared with 0.1 molar *tris* buffer, pH 7.0.

The experiments summarized in Table 1 showed that the coenzyme activity decreased rapidly but that the

Table 1. ACTIVITY OF THE NUCLEOTIDE PYROPHOSPHATASE OF *Tetrahymena pyriformis*

Time of incubation (min)	NAD ( $\mu$ -moles/mg of protein)	Phosphorus split ( $\mu$ g/mg of protein)	Potassium cyanide complex. Optical density at 340 m $\mu$ †
7	2.12	0.70	0.25
10	0.98	0.30	—
30	0.11	0.03	—
60	0.03	0.01	—
120	0.0	0.0	0.20
180	0.0	0.0	0.25
Heated at 70° C§	0.0	0.0	—
Incubated for 30 min with 3 mg of nicotinamide	0.12	0.0	—

\* Cell free sonicate (1 ml.) incubated with 7  $\mu$ moles of NAD and the activity measured with 0.1 ml. of 10 per cent ethanol, 1.8 ml. of 8.7 per cent sodium pyrophosphate, pH 9.5, and 0.1 ml. of alcohol dehydrogenase solution. Optical density measured in a spectrophotometer at 340 m $\mu$ .

† Phosphorus (acid soluble) was split by incubating 1 ml. of the sonicate extract, adjusted to contain 3 mg protein and 0.6 mg of NAD. Deproteinization with 12 per cent perchloric acid with 'Celite' as a filter aid. The centrifugate was assayed by Gomori's method and the colour was measured using a red filter in a photocolourimeter<sup>5</sup>.

‡ Cell free sonicate (0.2 ml.) was incubated with 0.2  $\mu$ moles of NAD and cooled; added with 1 molar potassium cyanide solution to make 3 ml. and the optical density was read at 340 m $\mu$  after 1 min<sup>4</sup>.

§ The extract (2 ml.) was heated in a water bath at 70° C for 2 min and cooled in an ice bath for the enzyme assay and determination of phosphorus. All these results represent mean values based on five separate experiments.

cyanide complex was unchanged even after 120 min of incubation. Acid soluble phosphorus increased with the time of incubation.

It is known that nicotinamide inhibits NADase and not pyrophosphatase; the enzyme from *Tetrahymena*, as expected, was not sensitive to nicotinamide (Table 1). Heating at 70° C for 2 min inactivated the enzyme, showing that a protein inhibitor is not present as in the case described for *Proteus vulgaris*<sup>7</sup>.

I concluded that the enzyme cleavage of NAD by sonicated extracts of *Tetrahymena pyriformis* is caused by a nucleotide pyrophosphatase and not NADase.

I thank the Conselho Nacional de Pesquisas for a fellowship, and Dr. S. H. Hutner, Haskins Laboratories, New York, for supplying the culture of *Tetrahymena pyriformis*.

### Electrophoresis of Glucose-6-phosphate Dehydrogenase: a New Technique

WE wish to report a new technique for the investigation of the electrophoretic behaviour of glucose-6-phosphate dehydrogenase (G6PD), which offers, in our opinion, some advantages over the starch gel technique used at present<sup>1,2</sup>.

The medium on which the electrophoresis is performed is cellulose acetate in a gel form ('Cellologel', manufactured by Chemetron, via G. Modena 24, Milano, Italy); this has already been used in investigations of the lactic dehydrogenase isozymes<sup>3</sup>. We use strips 4 cm wide, 17 cm long and 0.25 mm thick. It is advisable to make sure that the same batch of strips is used throughout each series of experiments. The electrophoresis buffer consists of 1 l. of 0.075 molar *tris* (containing 0.004 moles EDTA), to which is added 250 ml. of 0.075 molar citric acid solution; this gives a pH of 7.5.

The 'Cellogel' strips, which can be stored in 50 per cent methanol, are blotted with filter paper and soaked in buffer for at least 1 h. The operation is repeated with fresh buffer once or twice to ensure that the strips are completely free from methanol. They are then blotted again and placed in the electrophoresis tank (Shandon Universal Electrophoretic Tank MKII), well stretched, with the porous surface upwards. The plastic supports in the tank are adjusted to a distance of 9 cm, so that the terminal parts of the strips are immersed in the buffer and thus paper wicks are not required. The strips are equilibrated for about 10 min, with the current on (4 m.amp per strip). The current is then stopped and the samples are applied with a micro-pipette, in the form of thin streaks 12–13 mm long, at about 5 mm from the plastic support (cathodic end). The best results are obtained when only two samples are applied on each strip, leaving a free margin of about 5 mm on either side. Each sample consists of about 1.5  $\mu$ l. of haemolysate with an approximate concentration of 15 g per cent of haemoglobin. It is advisable to add some TPN to the haemolysate (0.10  $\mu$ moles/l. or less) before the run<sup>4</sup>.

Within about 1 min the samples are adsorbed on the gel, and the current is switched on. The run usually takes 3 h, at 4 m.amp per strip (constant amperage) and about 190 V.

A few minutes before the end of the run, the developing solution (ref. 5, modified) is prepared as follows:

Tris-HCl 1 mole/l. pH 8.6 (0.004 moles/l. in EDTA)	1.25 ml.
TPN (10 mg/ml.)	0.10 ml.
G6P (25 mg/ml.)	0.15 ml.
MTT tetrazolium (2 mg/ml.)	0.25 ml.
Phenazine methosulphate (2 mg/ml.)	0.25 ml.
Cobaltous chloride (0.5 moles/l.)	0.10 ml.

The total amount (2.1 ml.) is sufficient for the development of five strips. Tetrazolium and phenazine solutions are freshly prepared on each occasion. Cobaltous chloride forms an insoluble precipitate with the formazan originating from the tetrazolium<sup>6</sup>.

On completion of the run, the strips are cut free of the parts hanging in the buffer and marked. The developing reagent is poured on to a clean glass plate, and the strips are dipped into it one by one for about 5 sec, and gently blotted to remove any excess reagent.

The strips are now placed in a moist chamber, and the reaction is allowed to take place at 37° C for about 20 min. If the enzyme activity of the samples is high, the blue bands will appear almost immediately. The reaction is stopped by dipping the strips into a 10 per cent solution of formol. If the developed strips are kept in the dark in the formol solution at room temperature they can be preserved for about 2 weeks, but there is some fading of the colour. No fading of the colour will occur, however, if they are stored at -20° C.

Fig. 1 shows a typical electrophoresis pattern after the development of the enzyme bands. On each strip an artificial mixture of G6PD type A<sup>+</sup> and B<sup>+</sup> has been run together with a sample of type B<sup>+</sup>. The clear separation of the enzyme bands and the good reproducibility of the pattern can be observed. In the A<sup>+</sup>B<sup>+</sup> mixture, the A<sup>+</sup> enzyme has a lower activity due to long storage.

With fresh blood samples of type B<sup>+</sup> with a high enzyme activity, an "isozyme" band is often seen at about 6 mm behind the main B-band.

When this technique is compared with those utilizing starch gel<sup>1,2</sup>, the following advantages become evident: (a) only 3.5 h is required for the run and the development, as compared with 16–20 h when the starch gel technique is used; (b) it is not necessary to add TPN to the electrophoretic system because of the very small amount of heat generated in the strip and because of the short duration of the electrophoresis; (c) the run is performed at room temperature; (d) the amount of costly reagents (TPN,

Fig. 1. Electrophoretic patterns of G6PD A<sup>+</sup> and B<sup>+</sup> enzymes. On each strip is placed a mixture of A<sup>+</sup> and B<sup>+</sup> (left), and B<sup>+</sup> (right). The origin is at the cathode (bottom). The thin band behind the dark HbA band is HbA<sub>2</sub>.

G6P) required for the development is greatly reduced; (e) it is not necessary to prepare gel.

We think that this technique may prove to be a useful tool for population studies on G6PD, particularly because it is easy to perform under "field work" conditions.

From preliminary observations on samples kindly provided by Dr. Kirkman and on a series of haemolysates obtained from Indian tribal populations, we think that this technique is suitable not only for the discrimination of the "A" and "B" electrophoretic types of G6PD, but also for the detection of at least the most obvious electrophoretic variants.

### Effects of Pyruvate on the Formation of Urea in Rat Liver Slices

THE presence of the L-ornithine-pyruvate transaminase system in tissues has been well established<sup>1,2</sup>. In view of the possible presence of large concentrations of pyruvate (instead of the plasma lactate)<sup>3,4</sup> in the livers of tumour bearing rats, we have attempted to demonstrate the effect of this on the formation of urea.

Liver slices were prepared using a novel many-bladed slicer<sup>5</sup> and incubated for 100 min at 37.5° C in Krebs-

Ringer bicarbonate (KRB) pH 7.4 and the appropriate substrates with gas phase of 95 per cent O<sub>2</sub>: 5 per cent CO<sub>2</sub>. Substrates used were 10 millimolar pyruvate (P), 20 millimolar L-glutamine (G) and 0.3 millimolar L-ornithine (O). Liver with a wet weight of 50–100 mg was incubated in 3.0 ml. of medium in vessels such that adequate diffusion was possible for the liver slices, which were 0.4–0.6 mm thick. Samples of 2.0 ml. of incubation media were deproteinized<sup>6</sup> with barium hydroxide and zinc sulphate, and urea estimated by the Archibald method<sup>7</sup>. Amino-acids were separated electrophoretically (pyridine-acetic acid buffer pH 4.7 and acetic acid pH 2) and ornithine was estimated by the Chinard method<sup>8</sup>.

Table 1. EFFECT OF HIGH CONCENTRATIONS OF PYRUVATE ON UREA PRODUCTION AND ORNITHINE CONCENTRATION IN RAT LIVER SLICES

a			b		
Urea			Ornithine		
KRB	GO	GOP	KRB	GO	GOP
0.048	0.443	0.176	0.007	0.066	0.032
0.096	0.554	0.212	0.007	0.066	0.033
0.056	0.379	0.156	0.013	0.047	0.041
0.022	0.463	—	0.008	0.056	0.040
0.001	0.427	0.239	0.008	0.066	0.010
0.045	0.453 ± 0.064	0.196 ± 0.037	0.008	0.060 ± 0.0085	0.031 ± 0.0125
	1.96 < 0.453	(P < 0.005)		0.031 < 0.060	(P < 0.005)

KRB = Krebs-Ringer bicarbonate buffer; GO = KRB containing glutamine and ornithine; GOP = KRB containing glutamine, ornithine and pyruvate.

Each value given is a mean ± standard deviation of the results from 10 liver slices. Values are expressed in  $\mu$ moles of the substance changed in 100 min/ $\mu$ g dry weight tissue.

The results shown in Table 1 (a) indicate a decrease of about 50 per cent in the amount of urea formed from L-glutamine in the presence of high concentrations of pyruvate. There is also a decrease of about 50 per cent in the concentration of L-ornithine when it is present in excess—Table 1 (b). These results indicate that, contrary to the views of Bach *et al.*<sup>9</sup>, L-glutamine can be converted to urea via the Krebs ornithine cycle<sup>10</sup> (urea cycle). From these data it must be concluded that, under these experimental conditions, L-ornithine was channelled out of the urea cycle, and thus there is reduced urea production.

### Preferential *in vitro* Binding of Radioactive Vitamin B<sub>12</sub> by an Abnormal Serum Protein in Chronic Myeloid Leukaemia

ALTHOUGH considerable work has been done in the past decade on *in vivo* and *in vitro* binding of vitamin B<sub>12</sub> (refs. 1–4), the precise mechanisms of binding and the physiological significance of the binding patterns obtained remain uncertain.

*In vitro* binding of radioactive vitamin B<sub>12</sub> to normal serum proteins takes place principally in the  $\alpha_2$  and  $\beta$  fractions, while in chronic myeloid leukaemia the majority of radioactive vitamin B<sub>12</sub> is bound to a protein moving with the  $\alpha_1$  globulin fraction, possibly the seromucoid fraction<sup>5,6</sup>. Some authors hold that the increased binding capacity of myeloid leukaemia serum is caused by an increased amount of seromucoid fraction<sup>6</sup>; others dis-

Fig. 1. Column chromatogram of dialysed labelled normal serum. ●, Optical density at 280 Å; ×, radioactivity in counts per min above background. Changes in eluent were at tubes 17, 33 and 83.

Fig. 2. Column chromatogram of dialysed labelled serum from a patient with acute myeloid leukaemia, white cell count 360,000/mm<sup>3</sup>. ●, Optical density at 280 Å; ×, radioactivity in counts per min above background. The two highest points of radioactivity in peak V were 2,810 c.p.m. and 2,598 c.p.m. above background respectively. Changes in eluent were at tubes 16, 33 and 65.

agree<sup>7,8</sup>. It has also been suggested that the increase in binding to the  $\alpha_1$  fraction is a result of saturation of the "specific" B<sub>12</sub> binding proteins, and that the binding of added vitamin B<sub>12</sub> to other proteins is produced by an "overflow" effect<sup>8,9</sup>.

Recent studies have indicated that the binding of added cobalt-58 labelled vitamin B<sub>12</sub> (<sup>58</sup>Co-B<sub>12</sub>) to the serum proteins in chronic myeloid leukaemia is a preferential binding, and not an "overflow" phenomenon. Dialysed serum labelled with <sup>58</sup>Co-B<sub>12</sub> was obtained by a method previously described<sup>9</sup>, and column chromatography of the dialysed labelled serum was then carried out<sup>10</sup>.

A column of 'Sephadex DEAE-40' 15 cm × 1 cm was obtained by suspending approximately 1.8 g of DEAE in a solution of twice molar sodium chloride in 0.01 molar *tris* phosphate buffer pH 6.5; packing took place by gravity. Following equilibration with the buffer used for dialysis, a sample of dialysed labelled serum was placed on the column and a step-wise system of elution was used, starting with 0.01 molar *tris* phosphate buffer pH 6.5 and continuing to 0.20 molar *tris* phosphate buffer, pH 4.0. Each sample was counted in a well type scintillation counter, and its optical density was measured in an ultra-violet spectrophotometer at 280 Å. A chromatogram typical of normal labelled serum is shown in Fig. 1. Four major peaks are apparent, and are designated I, II, III-IV and V; complex III-IV is the most radioactive. The chromatogram shown in Fig. 2 is of dialysed labelled serum from a patient with myeloid leukaemia (white cell count 360,000/mm<sup>3</sup>); radioactivity in peak V was

				Total	Free
July 1961	7.9	161	1,452	2,864	80
Jan. 1963	10.6	27	2,200	1,530	0
April 1965	12.9	37.5	715	0	0
May 1965*	—	—	—	1,440	Most

\* After 2,000  $\mu\text{g}$  vitamin B<sub>12</sub> intramuscular injection.

in excess of 5,600 c.p.m. above background. Similar patterns have been obtained with sera from other patients with acute and chronic myeloid leukaemia. Purified labelled  $\alpha_1$  acid glycoprotein appears entirely at peak V when run on this type of chromatogram, indicating that the abnormal binding protein has mobility properties of an  $\alpha_1$  globulin.

Because of an unusual combination of clinical events, an opportunity was provided to study a patient with chronic myeloid leukaemia on several different occasions over a four-year period when the serum level of vitamin B<sub>12</sub> was successively elevated, low and then corrected therapeutically. The patient, who was diagnosed as having chronic myeloid leukaemia in 1961, had had a partial gastrectomy performed several years before. The binding capacity of her serum for radioactive B<sub>12</sub> was measured in 1963 and was found to be 7.36  $\mu\text{g}/\text{ml.}$  at the 10  $\mu\text{g}/\text{ml.}$  level. A sample of serum taken in 1961 was studied at the same time and showed similar results. In early 1965 the patient was found to have no vitamin B<sub>12</sub> detectable in her serum (see Table 1 for haematological data); presumably her deficiency had arisen because of her partial gastrectomy<sup>11</sup>. Column chromatography of dialysed labelled serum, collected at the time when the patient was deficient in vitamin B<sub>12</sub>, shows that all detectable vitamin B<sub>12</sub> is present in peak V; a 96 per cent recovery was obtained (Fig. 3). An identical pattern with 98 per cent recovery was obtained from dialysed labelled serum obtained after therapeutic vitamin B<sub>12</sub> had been given, at a time when her serum vitamin B<sub>12</sub> level was 1,440  $\mu\text{g}/\text{ml.}$ , mostly in the free form.

Fig. 3. Column chromatography of dialysed labelled serum from a patient with chronic myeloid leukaemia and no detectable vitamin B<sub>12</sub> in serum. ●, Optical density at 280 Å; ×, radioactivity in counts per min above background. No radioactivity was detected in fractions other than those shown. The radioactivity present accounts for 96 per cent of that placed on the column. Changes in eluent were at tubes 34, 85 and 116.

These results indicate that the abnormal protein present in the serum of myeloid leukaemia patients, possibly an  $\alpha_1$  acid glycoprotein, binds all added vitamin B<sub>12</sub> when vitamin B<sub>12</sub> deficiency is present. Thus the phenomenon of increased avidity for the vitamin appears to be specific and preferential, rather than an overflow phenomenon resulting from saturation of other binding sites.

These studies were initiated in the Clinical Research Unit of the Royal Prince Alfred Hospital, Camperdown, New South Wales. The work was supported by grants from the Post-graduate Medical Foundation of the

University of Sydney, the Burroughs Wellcome Foundation and the Leukemia Society, Inc. (U.S.A.).

### Evidence for a New Mechanism of Respiratory Stimulation and Proton Ejection in Ehrlich Ascites Tumour Cells dependent on Potassium Ions

OVER the past decade, evidence has accumulated that fragments of cellular membranes exhibit ATPase activity which is dependent on sodium ions and inhibited by ouabain, and which is probably involved in the active transport of sodium and potassium ions<sup>1</sup>. Another type of cation transport, characterized by an insensitivity to ouabain and coupled directly to the energy transfer system of the respiratory chain, has been demonstrated in isolated mitochondria. Interest in this system has been concerned primarily with the transport of divalent cations, and their exchange with hydrogen ions<sup>2</sup>, but it is now obvious that a similar mechanism can operate for the transport of monovalent cations, provided that the mitochondria are treated with certain polypeptide antibiotics. Valinomycin specifically promoted the uptake of potassium, rubidium and caesium ions<sup>3,4</sup>, whereas gramicidin also activated uptake of sodium and lithium ions by isolated mitochondria<sup>5</sup>.

A cell membrane mechanism dependent on sodium and potassium ions and sensitive to ouabain clearly exists in the intact cell, but the other mechanism for monovalent cation transport has only been demonstrated with isolated mitochondria. The results reported here suggest that valinomycin stimulated a mitochondrial exchange of hydrogen for potassium ions in the intact cell. The data also provide information about the quantitative importance of each of these two transport mechanisms and their interrelationship at the level of the intact cell. Investigations of the respiration and the concomitant ejection of protons by Ehrlich ascites tumour cells depleted of potassium provided evidence which is consistent with the operation of a dual mechanism for the active uptake of potassium ions in these cells. One mechanism which needs ATP is sensitive to ouabain and independent of valinomycin. The other mechanism is linked directly to the respiratory chain, is insensitive to ouabain, and is dependent on valinomycin. The data also indicate that each of the mechanisms contributes about a half of the total respiration which is dependent on potassium ions and about half of the proton release. Furthermore, the two mechanisms can operate independently.

Ehrlich ascites tumour cells collected from the peritoneal cavity of white mice 8–12 days after inoculation were placed in one of four different media buffered at pH 7.4 (the ionic composition of the media appears in figure and table legends). The cell suspensions were maintained at 4° C throughout all subsequent operations. The cells were separated from the ascitic fluid by centrifugation at 40g for 5 min, resuspended in the medium in which

they were collected, and then sedimented at 110g for 5 min. This procedure was repeated six times at 30 min intervals. The cells were finally sedimented at 250g for 5 min and resuspended in 2 volumes of the same medium. Suspended cells (1 ml.) were incubated with 4 ml. of the medium in which the cells were collected, but without the phosphate or *tris*-buffer. Incubations were carried out at 37° C. Oxygen uptake and release of hydrogen ions were detected and recorded continuously and simultaneously with an oxygen electrode and a glass electrode, respectively. The protein content of the cells was determined by the biuret method<sup>6</sup>. The concentration of potassium in the cells depleted of potassium ions, as determined with the flame spectrophotometer on an aliquot of supernatant solution from cells that had been treated overnight with 0.1 normal nitric acid, varied between 2 and 4 mequiv./l. of cells, which confirmed previous observations<sup>7</sup>. The volume of cells in suspension was determined by a micro haematocrit technique. Valinomycin was prepared and added to the incubation medium in alcoholic solution. Oligomycin, rotenone and antimycin A were added to the incubation medium in alcoholic solution; ethanol, in the concentration used, was without effect on the parameters investigated. The ouabain was dissolved in the medium and added to the incubation mixture in this form.

Addition of valinomycin to ascites tumour cells which were oxidizing endogenous substrate produced changes which were similar to those observed with mitochondria. An appreciable increase in respiration and in proton release (Fig. 1) was observed almost immediately after the addition of valinomycin. There was release of inhibition of respiration induced as oligomycin and extrusion of hydrogen ions was also apparent in the presence of valinomycin.

In order to decide whether the effect of valinomycin on oxygen uptake and the extrusion of protons was affected by potassium ions, it was necessary to deplete the cells of potassium ions. The response to valinomycin of cells depleted of potassium ions in a medium containing sodium ions, and in media in which the sodium was replaced by lithium or choline, was compared with cells prepared in the complete ("normal") medium (Table 1). Addition of valinomycin to cells depleted of potassium ions resulted in either an absence or a slight increase in oxygen uptake and release of hydrogen ions, in contrast to the marked stimulation observed with the normal cells. Further addition of potassium ions to the cells depleted of these ions resulted in a significant effect on both parameters; for the cells depleted in the media containing

Fig. 1. The effect of valinomycin on uptake of oxygen and release of hydrogen ions. The cells were collected and washed in the "normal" medium: 178 moles/l. of sodium; 6 moles/l. of potassium; 1.5 moles/l. of magnesium; 180 moles/l. of chloride; 1.5 moles/l. of sulphate, and 12 moles/l. of phosphate. Valinomycin was added to a final concentration of  $10^{-7}$  moles/l. In this and in all subsequent experiments. Oligomycin was present at a concentration of  $2 \mu\text{g/ml}$ . The protein content of the cells/5 ml. of incubation medium was 74.4 mg. \*

Table 1. RESPONSE OF NORMAL CELLS AND CELLS DEPLETED OF POTASSIUM IONS TO VALINOMYCIN

	Normal	Depleted of potassium ions		
		Sodium medium	Lithium medium	Choline medium
Uptake of oxygen ( $\mu\text{moles/mg protein/min}$ )				
Control	2.99	1.56	1.08	1.28
plus valinomycin	4.03	1.75	1.08	1.34
plus potassium ions	3.90	3.18	1.23	1.42
Release of hydrogen ( $\mu\text{moles/mg protein/min}$ )				
Control	2.2	1.3	0.8	0.7
plus valinomycin	3.5	1.5	1.0	1.0
plus potassium ions	3.7	3.0	1.7	0.7

The composition of the normal medium is detailed in the legend of Fig. 1. The composition of media for depleting cells of potassium ions was as follows: the sodium medium had 178 mmoles/l. of sodium; 1.5 mmoles/l. of magnesium; 154 mmoles/l. of chloride; 1.5 mmoles/l. of sulphate; 12 mmoles/l. of phosphate. The lithium medium had 178 mmoles/l. of lithium; 1.5 mmoles/l. of magnesium; 12 mmoles/l. of *tris* buffer; 166 mmoles/l. of chloride; 1.5 mmoles/l. of sulphate. Potassium ions were added to a final concentration of  $6 \times 10^{-3}$  molar and valinomycin to  $10^{-7}$  molar in this and all subsequent experiments. Cells (1 ml.) were added to 4 ml. of the appropriate medium. The protein content of the cells in each 5 ml. of incubation mixture was 76.2 mg of normal cells; cells depleted of potassium ions in sodium medium: 74.4 mg; in lithium medium: 74.4 mg; and in choline medium: 89.0 mg.

either sodium or lithium ions, the effect of valinomycin plus potassium ions in depleted cells in the choline medium was inconsistent and smaller. The changes observed after the addition of potassium ions to normal cells and to cells depleted of potassium ions are recorded in Table 2. A significant increase in respiration and release of hydrogen ions was observed with cells depleted of potassium ions in the sodium medium, but not in the lithium or choline media; addition of potassium to normal cells was without effect. Valinomycin caused a further augmentation of respiration and release of hydrogen in the depleted cells in the sodium medium and in normal cells; depleted cells in the lithium or choline medium responded to valinomycin with an initial increase in respiration and release of hydrogen. These observations suggested that the increase in oxygen uptake and hydrogen release on addition of potassium ions depleted cells in the sodium medium could be caused by the exchange of potassium ions for sodium ions and hydrogen ions across the plasma membrane. To evaluate this possibility further, transport of sodium was blocked by inhibiting ATPase of the membrane with ouabain (Table 3). Under these conditions, addition of potassium ions to cells which were depleted in the sodium medium was without effect on respiration

Table 2. RESPONSE TO POTASSIUM IONS OF NORMAL CELLS AND CELLS DEPLETED OF POTASSIUM IONS

	Normal	Sodium medium	Depleted Lithium medium	Choline medium
Uptake of oxygen ( $\mu\text{moles/mg of protein/min}$ )				
Control	2.88	1.63	1.12	1.03
plus potassium ions	2.93	2.31	1.08	1.01
plus valinomycin	4.14	3.38	1.35	1.44
Release of hydrogen ions ( $\mu\text{moles/mg of protein/min}$ )				
Control	2.4	1.1	1.0	0.6
plus potassium ions	2.6	1.9	0.7	0.7
plus valinomycin	3.9	3.2	1.7	1.4

The composition of the media and the protein content of the cells are indicated in the legend of Table 1.

Table 3. INFLUENCE OF OUABAIN ON RESPIRATION AND RELEASE OF HYDROGEN IONS

Additions	Uptake of oxygen ( $\mu\text{moles/mg of protein/min}$ )		Release of hydrogen ( $\mu\text{moles/mg of protein/min}$ )	
	without ouabain	with ouabain	without ouabain	with ouabain
Experiment 1				
Control	1.63	1.50	1.1	0.9

plus valinomycin	3.38	2.69	3.2	2.3
Experiment 2				
Control	1.56	1.30	1.3	0.9
plus valinomycin	1.75	1.50	1.5	1.1
plus potassium ions	3.19	2.26	3.0	1.9

Cells depleted of potassium ions (1 ml.) in the sodium medium (containing 74.4 mg of protein) were added to 4 ml. of the sodium medium without phosphate. The ouabain concentration was  $10^{-3}$  molar.

Fig. 2. Release of respiration by inhibited oligomycin and proton extrusion in cells depleted of potassium ions. The protein content of the cells/5 ml. of incubation medium was 74.4 mg. The final concentration of the additions was: 2  $\mu$ g/ml. of oligomycin,  $10^{-4}$  moles/l. of dinitrophenol.

and release of hydrogen. The expected effect of valinomycin was observed in every instance as long as potassium ions were present.

Addition of oligomycin to depleted cells in a medium containing sodium resulted in almost complete inhibition of respiration in a manner which had previously been observed with cells prepared in a normal medium without repeated washing<sup>8</sup>. Under these conditions, ATP production was inhibited and addition of potassium ions had little or no effect on either uptake of oxygen or release of hydrogen (Fig. 2). In agreement with results from isolated mitochondria<sup>9</sup>, further addition of valinomycin resulted in complete release of inhibition of respiration and release of protons. Thus, the effect of valinomycin on respiration and release of hydrogen in the presence of potassium ions was independent of ATP production; as shown before (Table 1), this effect of valinomycin was observed only when potassium was present. It has previously been suggested, on the basis of experiments with liver slices of which the activity is inhibited by oligomycin, that high energy intermediates other than ATP could provide energy for cation movements<sup>10</sup>. The release of respiratory inhibition induced by oligomycin by potassium ions plus valinomycin was similar to the release by dinitrophenol of respiration induced by oligomycin, except that the release by dinitrophenol was not dependent on the presence of potassium ions (bottom curve, Fig. 2).

The data of Table 1 indicated that neither sodium ions, lithium ions nor choline could effectively substitute for potassium ions in the intact cell system. Addition of either rubidium or caesium ions to the cells depleted of potassium ions in either the sodium, lithium or choline medium could replace potassium for demonstration of the valinomycin effect (Table 4), in agreement with results obtained with isolated mitochondria<sup>4</sup>. In other work with cells depleted of potassium ions and inhibited by oligomycin, either rubidium or caesium ions could support the valinomycin effect. The energy dependency of the two transport mechanisms for potassium ions in cells depleted of these ions was demonstrated by the data shown in Table 5. Ejection of protons by the cell preparations used in these experiments was undetectable in control conditions. Inhibition of the respiratory chain with rotenone (Experiment 1) or antimycin A (Experiment 2) blocked both the respiration dependent on potassium ions and the respiration stimulated by valinomycin and proton release. In contrast, inhibition of ATP formation with oligomycin (Experiment 3) markedly depressed respiration dependent on potassium ions, but not respiration stimulated by valinomycin and proton release. In Experiment 4, rotenone was seen to inhibit the mitochondrial exchange

of protons and potassium ions in the system when plasma membrane ATPase was blocked with ouabain.

The data presented here are consistent with the conclusion that Ehrlich ascites tumour cells which are depleted of potassium ions possess two mechanisms for active uptake of these ions from the medium: a plasma membrane component and a mitochondrial component (Table 6). Both are energy dependent, which was revealed by their sensitivity to respiratory inhibitors. The plasma membrane mechanism is inhibited by low concentrations of oligomycin, which indicates that it is dependent on ATP as the source of energy. It is dependent on the presence of sodium ions in the cells, for it is not observed when cells are prepared in the absence of sodium ions. It is independent of valinomycin and inhibited by ouabain. These are identical to the conditions necessary to identify the membrane ATPase activity which is thought to be associated with active transport of sodium and potassium ions<sup>1</sup>. ATP generated by glycolysis can support cell membrane transport of monovalent cations<sup>11</sup>. The mitochondrial mechanism is insensitive to oligomycin, which indicates that it can derive energy directly from high energy intermediates generated by the respiratory chain. It is dependent on valinomycin and insensitive to ouabain. It requires the presence of potassium, rubidium or caesium ions. These features are identical with those found for the cation-proton exchange induced by valinomycin in

Table 4. VALINOMYCIN EFFECT ON CELLS DEPLETED OF POTASSIUM IONS IN THE PRESENCE OF RUBIDIUM AND CAESIUM IONS

Additions	Uptake of oxygen ( $\mu$ moles/mg of protein/min)		
	Sodium medium	Lithium medium	Choline medium
Control	1.08	1.08	1.11
plus rubidium ions	1.35	1.08	1.11
plus valinomycin	1.74	1.23	1.37
Control	1.15	1.23	1.20
plus caesium ions	1.24	1.08	1.13
plus valinomycin	1.78	1.16	1.25
Additions	Release of hydrogen ( $\mu$ moles/mg of protein/min)		
	Sodium medium	Lithium medium	Choline medium
Control	0.8	1.2	0.5
plus rubidium ions	0.9	0.3	0.4
plus valinomycin	2.3	1.5	1.2
Control	0.9	1.0	0.2
plus caesium ions	1.0	0.3	0.2
plus valinomycin	2.2	1.3	0.6

Cells (1 ml.) were added to 4 ml. of the appropriate phosphate-free medium. The protein content of the cells in each 5 ml. of incubation medium was: cells depleted of potassium ions, 66.0 mg in sodium medium, 49.0 mg in lithium medium, and 77.0 mg in choline medium. Rubidium chloride and caesium chloride (40  $\mu$ l. of 0.75 molar solution) were added as indicated.

Table 5. RESPONSE OF CELLS DEPLETED OF POTASSIUM IONS TO INHIBITORS OF MITOCHONDRIAL METABOLISM

Additions	$\mu$ moles of oxygen/mg of protein/min	$\mu$ moles of hydrogen/mg of protein/min
Experiment (1) Control	2.45	0.0
plus potassium ions	3.50	2.8
plus valinomycin	4.52	4.6
plus rotenone	0.00	1.1
Experiment (2) Control	2.45	0.0
plus potassium ions	3.32	2.1
plus valinomycin	5.63	5.6
plus antimycin A	0.00	0.0
Experiment (3) Control	2.85	0.0
plus potassium ions	4.13	2.4
plus oligomycin	0.24	0.7
plus valinomycin	5.63	3.5
plus rotenone	0.00	0.0
Experiment (4) Control	2.22	0.0
plus potassium	3.17	2.1
plus ouabain	1.01	1.1
plus valinomycin	4.76	3.2
plus rotenone	0.00	0.0

The protein content of the cells/5 ml. of incubation medium was 58.6 mg. The final concentration of the additions were  $2 \times 10^{-4}$  molar rotenone; 2  $\mu$ g/ml. of oligomycin; 0.6  $\mu$ g/ml. of antimycin A;  $10^{-6}$  molar ouabain.

Table 6. CHARACTERISTICS OF RESPIRATION WHICH IS DEPENDENT ON POTASSIUM IONS AND RELEASE OF HYDROGEN

	Site

Sensitive to oligomycin	+	-
Dependent on sodium	+	-
Sensitive to ouabain	+	-
Sensitive to valinomycin	-	+

isolated mitochondria<sup>4</sup>. Advantage has been taken of the different characteristics of these two types of transport mechanism to demonstrate the independent operation of each in the intact cell.

In the presence of valinomycin, the mitochondrial mechanism can contribute as much as half of the total respiration and release of hydrogen ions by the cells, which is dependent on potassium ions. Whether, and to what extent, this represents a physiological reality will depend on the demonstration of the existence and the efficiency of naturally occurring agents which act like valinomycin. It is interesting that parathyroid hormone, which has been shown to enhance the uptake of magnesium ions by isolated liver mitochondria, has also been reported to stimulate the uptake of potassium ions by mitochondria<sup>12</sup>.

The results of this investigation indicate that activation of the cellular membrane transport system by the addition of potassium ions to cells which are loaded with sodium ions and depleted of potassium ions leads to stimulation of respiration and release of hydrogen ions. The increased respiratory response is a consequence of the activation of the pump for sodium ions, in agreement with the interpretation of Maizels *et al.*<sup>7</sup>. Evidence which supports the relationship between sodium transport and respiration has recently been summarized<sup>13</sup>. The release of protons is in some manner coupled with the sodium pump, for it is also blocked when transport of sodium and potassium ions are inhibited at the plasma membrane. The origin of the protons (whether mitochondrial or extramitochondrial) is an important question, but cannot be decided from the results of these experiments.

An intriguing feature revealed by the present work concerns the ability of the mitochondrial mechanism for uptake of potassium ions to operate even when the extramitochondrial mechanism is blocked by ouabain or oligomycin. This finding indicates that mitochondria might accumulate potassium ions from the extracellular medium when active transport of these ions across the cellular membrane is blocked. This interpretation implies that there exists a direct, functional communication between the extracellular fluid and the mitochondria. Demonstration of the absence of passive or facilitated transport of potassium ions across the cell membrane is, however, necessary before such an implication can be accepted with certainty.

## Effect of Growth Hormone on Tubular Reabsorption of Glucose and Phosphate

It is now well established that growth hormone has some renotropic properties. Besides its enhancing effect on renal plasma flow and glomerular filtration rate (GFR) in dog<sup>1,2</sup> and man<sup>3-5</sup>, growth hormone has been shown to raise tubular reabsorption of phosphate in man<sup>3-5</sup> and in normal and parathyroidectomized dogs<sup>6</sup>. In some respects, the mechanism of tubular transport of glucose is similar to that of phosphate; some common metabolic pathways are probably involved in their tubular transport since glucose has been shown to compete with phosphate for reabsorption<sup>7</sup>. It was therefore of interest to investigate the effect of growth hormone on tubular transport of glucose. For this purpose maximal tubular reabsorption of glucose (TmG) was measured before and after administration of bovine growth hormone (BGH) in the dog.

Unanaesthetized female mongrel dogs, weighing 15 to 20 kg, were used for these experiments and were fed freely.

TmG studies were done in five dogs. A priming injection of glucose and creatinine was given, then a sustaining solution containing glucose and creatinine was infused at a rate designed to maintain blood glucose and creatinine at a level adequate for GFR and TmG measurement. Glucose was measured in blood and urine by the method of Schaffer and Hartman<sup>8</sup>. Three days after the control experiment, administration of BGH (1.5 mg/kg/day) was begun. On the eighth and last day of BGH treatment, TmG was again measured in the same manner as before.

In a second group of dogs, parallel studies of the effect of BGH on maximal tubular reabsorption of phosphate (TmPO<sub>4</sub>) were performed, using the same pattern as for TmG. Methods were as previously described<sup>9</sup>.

The results are shown in Tables 1 and 2. TmG increased after growth hormone in all cases, although slightly in some of them. GFR also increased. The ratio TmG/GFR or mean renal threshold for glucose decreased in all experiments indicating a relatively smaller effect on glucose Tm than on filtration rate.

Table 1. EFFECT OF BOVINE GROWTH HORMONE ON MAXIMAL TUBULAR REABSORPTION OF GLUCOSE (TmG) AND GLOMERULAR FILTRATION RATE (GFR)

Dog	GFR (ml/min)		TmG (mg/min)		TmG/GFR × 100	
	A	B	A	B	A	B
IK	45.8	60.6	204	229	445	378
DO	49.9	61.5	225	238	452	388
TA	69.4	95.7	230	288	332	300
FR	41.0	58.3	179	230	436	398
LO	80.9	89.2	294	297	363	333

A: Control values.

B: After administration of bovine growth hormone (BGH).

Table 2. EFFECT OF BOVINE GROWTH HORMONE ON MAXIMAL TUBULAR REABSORPTION OF PHOSPHATE (TmPO<sub>4</sub>) AND GLOMERULAR FILTRATION RATE (GFR)

Dog	GFR (ml/min)		TmPO <sub>4</sub> (mg/min)		TmPO <sub>4</sub> /GFR × 100	
	A	B	A	B	A	B
TR	81.5	47.1	1.22	2.44	3.88	5.19
TA 1	81.4	120.3	3.19	7.01	3.82	5.83
2	93.3	123.6	3.78	5.81	4.06	4.69
FR	54.7	69.4	1.87	3.86	3.42	5.57
LO	91.7	107.7	4.07	5.34	4.44	4.96

A: Control values.

B: After bovine growth hormone administration.

In the experiments with TmPO<sub>4</sub> tubular reabsorption of phosphate increased much more than that of glucose, although the relative increase in GFR was no different from that in the TmG experiment. The ratio TmPO<sub>4</sub>/GFR increased in all experiments.

The action of growth hormone on the kidney for glucose excretion therefore appears to be different from phosphate excretion. Growth hormone tends to favour glucose excretion and to induce phosphate retention.

In physiological states the effect of growth hormone on glucose excretion is not apparent as blood glucose remains far below the renal threshold. In diabetes induced

by growth hormone, however, the action of growth hormone on the renal threshold could be a factor contributing to the glycosuria.

It is highly probable that growth hormone secretion plays a part in the physiological control of blood phosphorus and phosphaturia. The high concentration of phosphorus in the blood, as seen in active acromegaly, may be a result of the tubular effect of growth hormone. It has been shown that the maximum tubular reabsorption of phosphorus per unit of filtrate is increased in active acromegaly<sup>9</sup>.

### Synthesis of Zeatin, a Factor inducing Cell Division

COMPOUNDS which induce cell division in certain cultures of plant tissue have been termed cytokinins<sup>1</sup>. Zeatin, the first substance of this type to be isolated from a plant extract, has been shown to be 6-(4-hydroxy-3-methylbut-*trans*-2-enyl)aminopurine<sup>2</sup>. Shaw and Wilson<sup>3</sup> prepared 4-amino-2-methylbut-*trans*-2-en-1-ol from methyl tiglate and condensed it with 6-methylmercaptapurine to yield zeatin. An alternative synthesis for zeatin is now described. Values of the melting and boiling points are recorded for new compounds only. These all gave satisfactory elemental analyses.

Acetone was condensed with cyanoacetic acid in cyclohexylamine (compare ref. 4 where piperidine, a much more expensive solvent, is used) to give 3-methylcrotononitrile which was then brominated with *N*-bromosuccinimide, using benzoyl peroxide as catalyst, in boiling carbon tetrachloride to yield 4-bromo-3-methylcrotononitrile (I), boiling point 58°/0.9 mm. Since zeatin has a *trans* configuration, (I) and other intermediates are probably also *trans* structures. This was confirmed as follows: hydrolysis of (I) with 2 normal sodium hydroxide at 70° yielded an acid (isolated as the *S*-benzyl-*iso*-thiuronium salt, melting point 139°) identical with the 4-hydroxy-3-methylcrotonic acid which is prepared by alkaline hydrolysis of methyl 4-bromo-3-methylcrotonate<sup>5</sup> and which appears to possess a *trans* configuration<sup>6</sup>.

A mixture of (I), potassium acetate and acetic acid when heated under reflux yielded 4-acetoxy-3-methylcrotononitrile (II), boiling point 60°/0.08 mm. This was also prepared in much lower yield by the oxidation of 3-methylcrotononitrile with selenium dioxide in acetic anhydride. 4-Hydroxy-3-methylcrotononitrile (III), boiling point 74–75°/0.05 mm, was prepared by hydrolysis of (II) with dilute potassium hydroxide and then refluxed with 2,3-dihydropyran containing *p*-toluenesulphonic acid to yield the acetal 3-methyl-4-(tetrahydropyran-2-yloxy)crotononitrile (IV), boiling point 84°/0.08 mm. Reduction of (IV) with aluminium lithium hydride in ether gave the corresponding amine (tetraphenylborate, melting point 68–70°) which was hydrolysed at pH 0.6

at 20° to yield 4-amino-2-methylbut-2-en-1-ol (V). Attempts to prepare (V) by aluminium lithium hydride reduction of (II) yielded the saturated amine 4-amino-2-methylbutan-1-ol. (V) was condensed with 6-chloropurine in boiling butan-1-ol and the product (VI) recrystallized from ethanol.

Chromatography, spectroscopy (infra-red, ultra-violet, and nuclear magnetic resonance), mixed melting points, cell-division-promoting activity in carrot phloem cultures and oxidative degradation established that recrystallized (VI) and zeatin were identical. The structure already assigned to zeatin is thus confirmed. The reactions outlined above may be useful for preparing other unsaturated hydroxyamines.

### Fatty Acids of Fruiting Bodies of Basidiomycetes

ANALYSIS of the fatty acids of the mycelial lipids of a range of fungi, including basidiomycetes, grown in submerged culture on a defined medium has been described<sup>1</sup>. The fatty acids of some basidiomycete fruiting bodies, collected in the wild, have now been analysed.

A cluster of mushrooms (*Agaricus campestris*) and a group of toadstools (probably species of *Collybia*), each apparently representing one colony and homospecific, were gathered from pasture used by cows. A lobe of a bracket fungus (species of *Fomes*) was taken from the hawthorn on which it was growing. (*Agaricus* and *Collybia* are both in the family Agaricaceae, while *Fomes* is of the Polyporaceae.) The fructifications were washed, dried, macerated and extracted; the extract was saponified and the fatty acids were recovered, methylated and analysed by gas liquid chromatography, as before<sup>1</sup>. Table 1 shows the gross fatty acid compositions of the lipids extracted.

The stipe can be separated cleanly from the pileus in the toadstool and so these tissues were extracted separately for analysis of their fatty acids. The results are shown in Table 2. In the saponified lipids from each of the three types of fruiting body, there was a high proportion of linoleic acid, but little oleic acid. Previous results indicated that the fatty acids of mature basidiomycete mycelia characteristically included roughly equal parts of oleic and linoleic acid as major components<sup>1,2</sup>.

Lipids have been extracted from basidiomycete mycelia<sup>2</sup>, fruiting bodies<sup>3</sup> and certain pigmented surfaces<sup>4</sup>.

Table 1. FATTY ACIDS OF BASIDIOMYCETE FRUITING BODIES

	<i>Agaricus campestris</i>	Probably species of <i>Collybia</i>	Probably species of <i>Fomes</i>
Dry weight taken (g)	7.0	17.11	24.50
Saponifiable lipid (g)	0.35	0.47	0.51
Fatty acids (moles per cent)			
12:0	2.2	2.5	1.2
14:0	1.0	1.8	1.2
14:1	1.8	1.4	1.0
16:0	15.0	13.1	12.4
18:1	4.0	1.9	2.1
18:0	3.0	1.7	3.1
18:1	5.0	6.3	4.6
18:2	65.5	54.3	70.3
18:3	—	17.0	4.1
20:2	1.2	—	—
20:3	1.3	—	—

They have been divided into neutral and polar or phospholipid fractions and analysed with respect to the fatty acids produced by saponification. In each case, the neutral lipids contained a high proportion of oleic acid (31 per cent to 56 per cent) plus some linoleic acid (24 per cent to 32 per cent), while the polar or phospholipid fractions contained 67 per cent to 70 per cent linoleic acid, but very little oleic acid.

These results suggest that, apart from certain fluctuations which may occur in early growth<sup>2</sup>, the overall fatty acid composition of the lipids of a basidiomycete depends on the relative proportions of neutral and of polar lipids present; each gross fraction has its own characteristic fatty acid composition which does not vary markedly from species to species, or between vegetative and reproductive tissue in a given species<sup>2</sup>.

Table 2. FATTY ACIDS FROM PILEUS AND STIPE OF TOADSTOOL

	Pileus	Stipe
Dry weight taken (g)	8.56	8.61
Saponifiable lipid (g)	0.38	0.27
Fatty acids (moles per cent)		
12:0	1.9	3.7
14:0	1.5	2.6
14:1	1.3	1.4
16:0	14.4	10.4
16:1	1.5	2.8
18:0	1.5	2.0
18:1	3.9	11.1
18:2	62.0	39.0
18:3	12.0	27.0

The toadstool used was probably a species of *Collybia*.

The polar lipid fractions of basidiomycetes are evidently rich in linoleic acid, and so the high contents of linoleic acid reported here could be ascribed to the presence of a large polar lipid fraction, which is known to be the case in other basidiomycete fruiting bodies. The proportions of neutral and of polar lipid present in the fruiting bodies of *Clitocybe illudens* were found to be in the ratio 1:2 (ref. 3). In *Amanita muscaria* pigmented surfaces the ratio was 2:1 (ref. 4). Much of the lipid from the mycelium of a basidiomycete (*Tricholoma nudum*), especially in older cultures, is, however, neutral, with little polar lipid present<sup>2</sup>. It is evidently as a consequence of this that the lipids of basidiomycete mycelia are generally low in linoleic acid<sup>1,5</sup>, for in the mycelium of *T. nudum* any linoleic acid which is present is concentrated in a small phospholipid fraction<sup>2</sup>.

Table 2 shows that the composition of the fatty acids from the stipe is intermediate between that of the pileus and that reported for the mycelia of other basidiomycetes<sup>1,2</sup>.

The lower proportion of linoleic acid relative to other fatty acids found in vegetative as opposed to reproductive tissue of basidiomycetes suggests that linoleic acid may have a specific role in the reproductive mechanism of these fungi. The probability that this linoleic acid is largely combined in a polar lipid fraction makes a specific function more likely, by analogy with animals and plants the polar lipids of which are rich in certain polyunsaturated fatty acids which are believed to have specific functions related to their structure.

## Neuraminidase-like Enzyme present in *Mycoplasma gallisepticum*

*Mycoplasma gallisepticum* is the agent responsible for chronic respiratory disease in chickens. It will agglutinate mammalian and avian erythrocytes, and this phenomenon has been used to detect *M. gallisepticum* haemagglutinating inhibition antibodies. Two antigens have been used in the haemagglutination-inhibition (HI) test. The first will here be referred to as the "prepared antigen".\* This was obtained by growing the organism in broth, centrifuging and resuspending the organism in equal parts of glycerol and phosphate buffered saline (pH 7.0), freezing and storing until required for use, when it is further diluted in phosphate buffered saline. The other antigen is a rapidly growing 24 h broth culture grown in PPLO broth, 10 per cent horse serum, 1 per cent yeast autolysate, and 0.1 per cent dextrose, with the pH adjusted to 7.8 (ref. 1).

When the prepared antigen was used in the HI test, haemagglutination was often inhibited by normal chicken serum<sup>2</sup>, and the titres ranged from 1/5 to 1/20 when titrated against four haemagglutination (HA) units. We have found that these non-specific HI titres obtained with the prepared antigen were removed when the sera were first treated with neuraminidase or sodium metaperiodate. Non-specific HI titres were not obtained when the broth antigen was used<sup>1,3</sup>.

It is well known that  $\alpha$ -inhibitors of influenza virus haemagglutination have a similar chemical structure to erythrocyte receptors for myxoviruses. These inhibitors exist in chicken serum<sup>4</sup> and it seems likely that the same  $\alpha$ -inhibitors caused the non-specific inhibition when the prepared antigen of *M. gallisepticum* was titrated against normal serum in the HI test. A neuraminidase-like enzyme was present in *M. gallisepticum*; it was active in the broth antigen but inactive or absent in the prepared antigen. The non-specific inhibition, seen with the prepared antigen, may have resulted from the effect of phosphate buffered saline on *M. gallisepticum*. Alternatively, it may have occurred because the neuraminidase-like enzyme is extracellular, as with certain clostridia, and was removed when the prepared antigen was made up. When *M. gallisepticum* was suspended in phosphate buffered saline, 81 per cent of the organisms were dead within 4 h. It seems probable that the prepared antigen diluted in phosphate buffered saline behaves in much the same way as indicator influenza virus when they are titrated against normal chicken serum.

The effect of neuraminidase treatment on the agglutination of chicken erythrocytes by *M. gallisepticum* was investigated. Neuraminidase diluted in calcium saline was added to a 1 per cent suspension of chicken erythrocytes; the mixture was then incubated at 37° C. Aliquots were removed at intervals, centrifuged and washed three times in sodium citrate saline, and resuspended in physiological saline to a concentration of 1 per cent. Chicken erythrocytes suspended in calcium saline without neuraminidase were treated similarly and served as controls. The haemagglutination titres of treated and control cells by *M. gallisepticum* were then assessed, using 4 HA units of prepared antigen. Receptors for *M. gallisepticum* were not destroyed after incubation for 8 h at 37° C.

The failure of neuraminidase to remove receptors to *M. gallisepticum* was in marked contrast to the successful removal of receptors to the WR1 strain of avian mycoplasma; the receptors to WR1 were removed after the erythrocytes had been treated for 1 h with neuraminidase<sup>5</sup>. When the WR1 strain was used in the HI test, non-specific inhibition of agglutination was seen with both the prepared and broth antigens when these were titrated against normal chicken serum. This neuraminidase-like enzyme thus appears to be absent in the WR1 strain.

Neuraminidase activity of myxoviruses has been attributed a role in cell penetration<sup>6,7</sup>. The pathogenicity of *M. gallisepticum* may be attributed to the neuraminidase-like enzyme; this enzyme is absent in the WR1 strain and this organism is non-pathogenic for chickens<sup>8</sup>. The ease with which cell receptors to avian mycoplasma are removed by neuraminidase may also be an indication of pathogenicity. It is interesting to note that an antibody response to *M. anatis* in ducks was not stimulated without the presence of an influenza A virus<sup>9</sup>.

### Stability of Dextran during Prolonged Storage

MEASUREMENTS made on clinical dextran solutions after storage at 4° C for 5 years revealed no significant deterioration<sup>1</sup>. These measurements have now been repeated after 10 years. Dextran solutions A and B were made in the United States and C and D in Great Britain. Where applicable the methods of testing described in the *British Pharmacopoeia* were used and, as before, the specific optical rotation of each dextran was used in calculating the concentrations of solutions for the viscosity measurements. Table 1 records the intrinsic viscosity measurements. Dextran A, B and C showed relatively small changes even after 10 years; there was certainly no sign of progressive change. Dextran D had given some indication of change at 5 years. Two bottles of this dextran were examined after 10 years. The intrinsic viscosities were 0.352 and 0.356; their mean is entered in Table 1.

The renal excretion of these dextrans in rabbits is shown in Table 2. Two rabbits were used for each determination (1965) and the daily results averaged; Table 2 shows totals for 3 days after injection. After 5 years storage there appeared to have been an increase in the renal excretion of dextran A, but this was not corroborated by other measurements made at the time or more recently.

Table 1

Dextran	Intrinsic viscosity at 25° C		
	1954	1959	1965
A	0.249	0.248	0.248
B	0.254	0.251	0.252
C	0.304	0.383	0.394
D	0.362	0.326	0.354

Table 2

Dextran	Percentages of injected dose excreted		
	1954	1959	1965
A	37.2	47.6	43.8
B	43.1	39.1	46.7
C	13.5	14.6	15.0
D	15.9	15.4	21.1

Table 3. PLASMA CONCENTRATION OF DEXTRAN AS A PERCENTAGE OF CONCENTRATION 10 MIN AFTER INJECTION

Dextran		Day			
		1	2	3	4
A	1954	23.8	11.7	0.4	0.0
	1959	29.6	15.2	2.25	0.8
	1965	23.5	11.3	2.1	0.1
B	1954	29.2	13.8	3.6	0.0
	1959	30.0	14.1	2.0	0.6
	1965	29.4	12.4	2.9	0.1
C	1954	56.8	34.6	12.3	3.8
	1959	61.0	40.9	18.3	10.0
	1965	51.7	33.5	9.2	6.9
D	1954	60.5	40.2	22.8	12.8
	1959	56.6	38.7	22.0	—
	1965	42.0	30.4	20.1	10.3

The retention of each dextran in the plasma was determined by taking the average of daily estimations in the two rabbits. Table 3 shows that little if any change had occurred in the dextrans, apart possibly from dextran solution D, affecting their retention in the circulation.

The original and subsequent measurements of intrinsic viscosity, renal excretion, and retention in the plasma of dextran solution D may indicate that some hydrolysis occurred.

From our observations we conclude that during the 10 year period there was little, if any, change in the molecular composition, with the possible exception of dextran solution D. The change observed in this solution, however, would not be noticeable in clinical use. These results were obtained with 6 per cent dextran in 0.9 per cent sodium chloride in glass bottles with rubber closures and are not necessarily valid for other containers or other solvents, for example, dextran in 5 per cent glucose solution. Probably a dextran of molecular weight intermediate between those tested would be equally stable; measurements have not been made on dextrans of lower molecular weight. Little or no deposit was seen in any of the bottles.

## HAEMATOLOGY

### Inheritance and Sub-unit Composition of Haemoglobin in the Horse, Donkey and their Hybrids

INVESTIGATIONS of mammalian haemoglobins have given much biological information<sup>1-3</sup>, but although notable advances, particularly in human haemoglobins, have been made, many aspects of the subject remain obscure or hypothetical. The genetics of haemoglobin is particularly in need of clarification. Valuable genetic information has been acquired from the use of model hybrid systems<sup>4,5</sup>, and the findings complement information laboriously obtained from investigation of occasionally suitable human families. We have investigated the pattern of inheritance of haemoglobins in the Equidae and their interspecific hybrids, in which the karyotypes of the individual species have been well defined<sup>6</sup>, by electrophoresis, peptide mapping, and separation of globin sub-units.

Fig. 1. Electrophoretic patterns on cellulose acetate of whole haemoglobins from the horse, donkey and their hybrids. (1) Female hinny; (2) male hinny; (3) female horse; (4) male horse; (5) female mule; (6) male mule; (7) female donkey; (8) male donkey.

Nine horses, five donkeys, two hinnies and eleven mules were used. Haemoglobin solutions were prepared according to Ingram, with minor modifications<sup>7</sup>, and stored at  $-20^{\circ}\text{C}$  until used. Electrophoresis of these solutions was carried out on cellulose acetate using a *tris*-hydrochloric acid buffer<sup>8</sup>, ethylene diamine tetraacetic acid-borate-*tris* (EBT) buffer at pH 8.8 (ref. 9). Cellulose acetate (Fig. 1) and starch gel electrophoresis (Fig. 2) of haemoglobin of horse, mule and hinny showed two bands, the rates of migration of which were identical in the three species. The donkey showed a single band only, corresponding to the cathodic band of the horse, mule and hinny. Sex differences were not noted.

Peptide mapping was carried out by a modification of Ingram's procedure<sup>7</sup>, that is, heat denaturation and tryptic digestion, chymotrypsin in the enzyme preparation being inhibited by 0.5 per cent 1-1-tosyl amido-2-phenylethyl chloromethyl ketone (TPCK)<sup>10</sup> at  $37^{\circ}\text{C}$  for 48 h, followed by electrophoresis on Whatman No. 3 paper (18 in.  $\times$  22 in.) in pyridine, acetic acid and water (10:0.4:90), followed after drying by descending chromatography for 15 h with pyridine, iso-amyl alcohol and water (30:30:35) as solvent. The colour was developed with ninhydrin after drying. Peptide maps yielded some differences: the donkey, mule and hinny were almost identical, but the horse differed from these in several peptides.

Globin was prepared from the dialysed haemolysate and separated electrophoretically on starch gel using a urea-veronal buffer at pH 8.0, according to Chernoff and Pettit<sup>11</sup>, to determine the number and the electrophoretic properties of the haemoglobin sub-units. Similarly, globin was prepared from the various haemoglobin solutions after electrophoresis on starch gel using EBT buffer<sup>9</sup>, by eluting each haemoglobin separately. Globin prepared from the eluate of each band was separated electrophoretically on urea-veronal starch gel as mentioned previously. The sub-units of each haemoglobin band could then be identified by staining with 1 per cent amido black B as described by Fine<sup>12</sup>.

The separation of sub-units of globin prepared from whole haemoglobins showed that the horse, mule and hinny globins separated into three bands—two cathodic and one anodic (Fig. 3). The globin of the donkey differed in having only two bands. When compared with human haemoglobins A and S as reference standards, the faster cathodic band of all four species migrated at the same rate as the  $\alpha$ -chains of human haemoglobin A. The anodic bands in all cases moved more rapidly than the  $\beta$ -bands of haemoglobin A.

The globin recovered from the faster haemoglobin bands of all four animal types on EBT-starch gel consisted primarily of the  $\beta$  sub-units and the slow  $\alpha$  sub-units. The globin prepared from the slower bands contained  $\beta$  sub-units and the faster  $\alpha$  sub-units. These results were consistent in horse, mule and hinny. Globin derived from the single haemoglobin species of the donkey behaves identically with that of the slow bands of the other animals (Fig. 4).

The data presented demonstrate that the two haemoglobins of horse, mule and hinny are composed of three polypeptide sub-units the  $\beta$ -band of which is common to both. This is clearly shown by the results of urea-starch gel electrophoresis (Fig. 3), in which the three sub-

Fig. 2. Electrophoretic patterns on starch gel of whole haemoglobins of horse, donkey, and their hybrids, and artificial mixtures of horse and donkey haemoglobins in varying proportions. (1) Male donkey; (2) male horse; (3) male hinny; (4) male mule; (5) horse: donkey 50:50; (6) horse: donkey 20:80; (7) horse: donkey 40:60; (8) horse: donkey 60:40; (9) horse: donkey 80:20; (10) horse: donkey 80:20.

Fig. 3. Separation on urea-starch gel of globin sub-units derived from human A and S, donkey, horse, mule and hinny haemoglobins. Globin sub-units prepared from: (1 and 6) mule; (2 and 7) horse; (3 and 8) hinny; (4 and 9) donkey; (5 and 10) human A and S.

Fig. 4. Identification on urea-starch gel of the globin sub-units derived from the fast and slow haemoglobin bands of the mule and hinny. (1) Donkey globin-whole haemoglobin; (2) slow band, male mule; (3) fast band, male mule; (4) male mule globin, whole haemoglobin; (5) slow band, female mule; (6) fast band, female mule; (7) female hinny globin, whole haemoglobin; (8) slow band, female hinny; (9) fast band, female hinny; (10) horse globin, whole haemoglobin.

units are illustrated. If globin from individual haemoglobin bands is similarly treated, each separates into an anodic and a cathodic band. The cathodic bands are electrophoretically identical, while the anodic bands migrate at different rates (Fig. 4).

Whole haemoglobins separated on paper electrophoresis have given results very similar to those found on EBT-starch gel, and suggest that in the mule and hinny three haemoglobins could exist—two from the horse and one from the donkey<sup>13</sup>. This matter could not be resolved satisfactorily by electrophoresis of mixtures of horse and donkey haemoglobin in varied proportions (Fig. 2).

Electrophoretic study of the globin sub-units derived from donkey haemoglobin yields two sub-unit fractions identical in mobility to the fractions of the comparable haemoglobin band of the horse, but this does not eliminate the possibility of electrophoretically silent differences. That human and horse  $\alpha$ -chains, which are known to be chemically different, migrate identically in this system supports the probability of biological differences. Results of peptide mapping, though not conclusive, also lend support.

## Interaction of Plasma Kinins and Granulocytes

KININS are polypeptides derived from naturally occurring plasma protein substrates (kininogen). The known kinins have been synthesized and are nonapeptides, decapeptides or undecapeptides<sup>1</sup>. Five principal pharmacological actions have been attributed to plasma kinins: stimulation of some smooth muscle, increase in vascular permeability, vasodilation, leucotaxis and induction of pain<sup>2</sup>. These actions are the cardinal manifestations of inflammation. It is not surprising, therefore, that kinins have been implicated among the mediators of the response of tissue to injury. The nonapeptide (bradykinin) can evoke an inflammatory response when applied to subcutaneous tissues<sup>3</sup>. Kinin levels increase at the site of inflammation caused by burns<sup>4</sup>, and during acute arthritis<sup>5</sup>.

We investigated the interaction between kinins and leucocytes, the principal cellular component of inflammation, and found that granulocytes caused a rapid but transient liberation of kinins from whole plasma and purified plasma substrate. The kinins formed in this

way were destroyed slowly by intact granulocytes or granulocyte fragments. Neither granulocyte metabolism nor phagocytosis was affected by bradykinin. Using these observations, we have formulated a model of the interaction of granulocytes and the plasma kinins in inflammation.

Leucocytes were obtained from the heparinized venous blood of normal subjects, patients with polycythaemia vera and patients with arteriosclerosis. The preparation of the samples has been described previously<sup>6,7</sup>. The separation of lymphocytes and the *in vitro* incubation conditions have also been described in detail<sup>6,7</sup> and were modified only by the use of Eagle's minimal essential medium<sup>8</sup> containing 25 mg/ml. human albumin as the suspending medium. The methods used to measure the conversion of glucose-1-<sup>14</sup>C to <sup>14</sup>CO<sub>2</sub>, incorporation of <sup>14</sup>C-amino-acids into protein, and of tritiated uridine into ribonucleic acid, lactate production, granulocyte acid-phosphatase activity, and the quantitation of the phagocytosis of polystyrene particles by granulocytes have all been reported<sup>6</sup>.

Various cells or cell fractions were incubated with (1) plasma; (2) purified  $\alpha_2$  globulin substrate (kininogen) prepared by a minor modification of the method of Webster and Pierce<sup>9</sup> and free of kininase and kinin generating activities; or (3) with synthetic bradykinin. The concentration of biologically active peptides was measured by bioassay<sup>10</sup> using synthetic bradykinin as the standard. The peptides were characterized by their insensitivity to trypsin, their inactivation by chymotrypsin and by their hypotensive effect on rats. The concentration of kininogen in plasma or substrate was calculated from the difference between kinin levels before (spontaneously formed kinin) and after the trypsin reaction described by Diniz and Carvalho<sup>11</sup>. Because kinins were simultaneously released from the substrate and destroyed by the activity of plasma and granulocyte kininase, their concentration at any time was a function of these two opposing processes. Consequently, the fall in substrate concentration was used as a measure of the total generation of kinin.

The addition of leucocytes (60–80 per cent granulocytes and 20–40 per cent lymphocytes) to cell-free plasma or serum at pH 7.4–7.6 increased the plasma kinin concentration two to three times and decreased the substrate about the same amount (Fig. 1 and Table 1, Series 1). The changes occurred within 5 min of addition of the cells, both at 20° and 37° C. Only white cell populations containing at least  $0.5 \times 10^6$  granulocytes/ml. of incubate produced kinin. Normal and neoplastic lymphocytes (94–98 per cent lymphocytes and 1–2 per cent neutrophils) were inactive (Fig. 1) at concentrations up to  $3 \times 10^7$  cells/ml. The generation of kinin was proportional to the concentration of granulocytes and occurred at physiological granulocyte levels (Table 1, Series I). Thus, neutrophils and myelocytes, at concentrations of  $3 \times 10^6$ /ml., converted an amount of substrate corresponding to

Fig. 1. A representative experiment depicting the effects of addition of various leucocytes to plasma. The kinin concentration rose and kininogen concentration fell after granulocytes were added to plasma (left). • Lymphocytes did not alter either concentration.

approximately 50 per cent of the initial plasma concentration to kinin within minutes.

To determine whether granulocytes were capable of generating kinin directly from substrate, well washed cells ( $3 \times 10^6$ /ml.) were added to purified kininogen (1,000  $\mu\text{g}/\text{ml}.$ ) suspended in saline. Within 30 min, the cells had converted 750  $\mu\text{g}/\text{ml}.$  of substrate to active peptide (Table 1, Series II).

Generation of kinin by granulocytes appeared to require protein and RNA synthesis and an intact glycolytic pathway as this activity was partially inhibited by  $2 \times 10^{-2}$  molar sodium fluoride, by  $4 \times 10^{-5}$  molar puromycin and by 5  $\mu\text{g}/\text{ml}.$  actinomycin D (Table 1, Series III). These levels of puromycin and actinomycin inhibit 90–95 per cent of protein and RNA synthesis, respectively, in granulocytes within 10 min. Kinin generation by white cells was completely inhibited by  $2.6 \times 10^{-6}$  molar cortisol but not by corresponding concentrations of deoxycorticosterone (Table 1, Series III).

The kinin formed when granulocytes were added to plasma disappeared within 60–120 min. The peptides could have been destroyed or inactivated by either plasma kininase or leucocyte kininase. When we incubated 2  $\mu\text{g}/\text{ml}.$  of synthetic bradykinin with  $3 \times 10^6$ /ml. well washed leucocytes at 37° C, the following observations were made (Table 2). Intact granulocytes but not lymphocytes had kininase activity and destroyed approximately 0.5–0.9  $\mu\text{g}$  of bradykinin/h/ $10^6$  cells. Kininase activity was not affected by incubating intact leucocytes with  $4 \times 10^{-5}$  molar puromycin or  $6 \times 10^{-5}$  molar cortisol, but was partially inhibited by  $2 \times 10^{-2}$  molar sodium fluoride. When granulocytes were disrupted by sonication in 0.1 molar *tris* buffer, pH 7.4, the specific kininase activity was greatest in that fraction which did not sediment at 100,000g (60 min). The pH optimum of soluble granulocyte kininase activity was between 7.0 and 7.4 (Fig. 2).

Table 1. KININ FORMATION AFTER ADDITION OF HUMAN LEUCOCYTES TO NORMAL PLASMA OR PURIFIED KININOGEN\*

Cell type (concentration $\times 10^6$ /ml.)	No. of experi- ments	Compound added (concentration)	Kinin con- centration (% of control)	Kininogen remaining (%)
Series I				
Substrate: plasma (2,810–4,670 $\mu\text{g}$ kininogen/ml.)

Granulocytes (3)	3	Deoxycorticosterone ( $4 \times 10^{-6}$ mmoles/ml.)	350 $\pm$ 104	37 $\pm$ 9

\* Granulocyte preparations contained an average of 83 per cent neutrophils and 13 per cent lymphocytes. Leucocytes or cell-free incubation medium were added to plasma or purified kininogen and the concentrations of kinins and kininogen were determined after 10 min. The control samples contained no added cells. All values for kinin and kininogen concentration are expressed as the per cent of control and are the mean values  $\pm$  S.E.

Table 2. KININ DESTRUCTION BY HUMAN LEUCOCYTES (KININASE ACTIVITY)\*

Cells added	No. of experiments	Drugs added (mmoles/ml.)	Kinin remain- ing (per cent)
None	6		90 $\pm$ 3
Granulocytes	6		31 $\pm$ 6
Granulocytes	3	Sodium fluoride ( $2 \times 10^{-2}$ )	45 $\pm$ 8
Granulocytes	2	Cortisol ( $2.5 \times 10^{-6}$ )	46 $\pm$ 10
Granulocytes	4	Puromycin ( $4 \times 10^{-5}$ )	33 $\pm$ 9
Lymphocytes	4		84 $\pm$ 6

\* Synthetic bradykinin (1,000–7,980  $\mu\text{g}/\text{ml}.$ ) was added to leucocytes or cell-free medium and incubated for 60–120 min. All values were expressed as the per cent of the bradykinin concentration present at the initiation of incubation and are given as the mean  $\pm$  one S.E. of the mean. In all experiments the cell concentration was  $3 \times 10^6$ /ml.

Fig. 2. Study of kininase activity of granulocytes. The S-100 supernatant fraction of sonicated granulocytes contained greatest kininase activity (left). The pH optimum of the kininase was near physiological levels.

Kinins are leucotactic and are concentrated at the sites of inflammation. If phagocytic leucocytes are to function in such an environment, they should be able to withstand exposure to high concentrations of kinins. We determined the incorporation of tritiated uridine into RNA and  $^{14}\text{C}$ -amino-acids into protein, the conversion of glucose-1- $^{14}\text{C}$  to  $^{14}\text{CO}_2$ , the production of lactic acid, acid phosphatase activity, and the phagocytosis of polystyrene particles by granulocytes. Synthetic bradykinin had no significant effect on these functions (Table 3).

Table 3. EFFECT OF BRADYKININ ON GRANULOCYTE METABOLISM\*

Function	No. of experiments	Without bradykinin	With bradykinin
RNA synthesis (c.p.m./ $\mu\text{g}/\text{h}$ )	7	1,184 $\pm$ 69	1,139 $\pm$ 25
Protein synthesis (c.p.m./ $10^6$ cells/h)	6	971 $\pm$ 34	954 $\pm$ 53
Lactate synthesis ( $\mu\text{g}/10^6$ cells/h)	4	134 $\pm$ 7	135 $\pm$ 7
Conversion glucose-1- $^{14}\text{C}$ to $^{14}\text{CO}_2$ (c.p.m./h/ $10^6$ cells)	3	1,630 $\pm$ 112	1,433 $\pm$ 378
Acid phosphatase ( $\mu\text{g}$ phosphorus/3 $\times 10^6$ cells/h)	6	71.2 $\pm$ 4.9	70.3 $\pm$ 1.6
Polystyrene ingestion (per cent of cells containing more than six par- ticles per cell)	3	60	70

\* All incubations were for 60 min after the addition of 50–100  $\mu\text{g}$  synthetic bradykinin/ml. of solution.

The results of our studies indicate that human granulocytes can generate and can destroy kinins, but normal or neoplastic lymphocytes cannot. High concentrations of bradykinin have no effect on any of the observed parameters of the metabolism of granulocytes. Kininase activity is present in disrupted as well as intact granulocytes and is most pronounced near physiological pH values. Puromycin, sodium fluoride and cortisol inhibit kinin production but have relatively little effect on kininase activity. According to a preliminary report<sup>13</sup>, many of these observations appear to be equally true for leucocytes of rabbits obtained in peritoneal exudates.

The mechanism of the release of kinin from substrate by intact granulocytes is not immediately apparent. One might reasonably ask why granulocytes are not continuously generating kinin *in vivo* as they circulate in the bloodstream. A possible answer may be that the manipulations involved in the isolation and incubation of leucocytes alter the cells in some way so that leucocyte kallikrein activity is "unmasked" without altering other granulocyte functions such as phagocytosis. If leucocytes are intentionally damaged by repeated cycles of washing and incubation, however, they lose their kallikrein activity. Therefore, a certain amount of damage to granulocytes may be necessary to unmask kallikrein activity.

We propose the following hypothesis of the interaction of granulocytes and kinins in inflammation. Injured tissue activates Hageman factor which releases kinin<sup>12</sup>; kinins thus released contribute to the signs of inflammation, including capillary and arteriolar dilatation with increased blood flow, and increased capillary permeability, and oedema. The kinins attract intact phagocytes which migrate to the walls of the blood vessels at the site of

injury<sup>3</sup>. The granulocytes, in turn, release more kinin from the available substrate and accelerate the inflammatory process. As the granulocytes accumulate and disintegrate, more kinins are destroyed than are formed and (as in our *in vitro* system) kinin levels fall. The character of a local inflammatory reaction would thus reflect complex interrelationships between kinins and granulocytes and undergo a gradual transition from the manifestations of kinin action to those of leucocyte accumulation.

## PHARMACOLOGY

### Blockade by Propranolol of the Effect of Isoprenaline on Heart Rate and its Reversal by Methamphetamine

THE adrenergic receptors have been broadly classified into two groups: alpha and beta<sup>1</sup>. Adrenergic receptors present in the mammalian cardiac muscle are now thought to belong to the beta type, and to initiate stimulation when occupied. Isoprenaline<sup>2</sup> is the catecholamine which best fits the beta receptor. The recently introduced drug propranolol hydrochloride (I.C.I. 45520; 'Inderal') is a

electrocardiograph. All solutions were made up in distilled water.

In eight dogs, isoprenaline sulphate 1 µg/kg, injected intravenously over a period of 10 sec (10 µg/ml. solution), produced a marked increase in heart rate (mean  $32.29 \pm S.D.$  7.92 per cent). There was a marked fall in blood pressure (mean 52, range 42–68 mm of mercury). Both the heart rate and the blood pressure returned to normal in 5–7 min. After recording two control responses to isoprenaline in each animal, a 0.1 per cent solution of propranolol hydrochloride 0.3 mg/kg was injected intravenously. This drug produced a distinct decrease in the heart rate. The maximal effect was seen in about 5 min. 10 min after administration of propranolol, the injection of isoprenaline was repeated. There was no increase in heart rate in six experiments, while in two experiments the rate was increased by 6 and 12 beats/min. The heart rate did not return to control levels in either of these experiments (Table 1). The mean reduction in the effect of isoprenaline produced by propranolol was 96 per cent. The fall in blood pressure was completely blocked, and a brief pressor response was seen with isoprenaline (10–15 mm mercury). Another dose of isoprenaline also produced similar results. Methamphetamine 0.3 mg/kg, injected intravenously (0.1 per cent solution), produced a sustained rise in blood pressure (28–46 mm mercury). The heart rate increased gradually in five experiments, and in one of these experiments it reached the control level before propranolol was administered. In the remaining three experiments there was no increase in heart rate after methamphetamine. Injection of isoprenaline was then repeated. This drug now again increased the heart rate (mean  $21.10 \pm S.D.$  5.26 per cent). This increase in rate was 34.64 per cent less than that produced in controls before propranolol injection. The results are summarized in Table 1. The blood pressure response was now biphasic; a brief pressor response (10–15 mm mercury) was followed by a brief depressor response (15–20 mm mercury). An increase in the dose of methamphetamine did not fully restore the effect of isoprenaline on heart rate. Similarly, a purely depressor response to isoprenaline could not be restored.

In the remaining four dogs, propranolol completely blocked the effect of isoprenaline on the heart rate. Repeated injections of adrenaline hydrochloride and noradrenaline bitartrate (5 µg/kg), ephedrine sulphate and methoxamine (0.3 mg/kg) failed to restore the isoprenaline response. The reversal of the blocking action of pro-

potent blocking agent for beta receptors, and it has been shown to block the action of isoprenaline in increasing the heart rate (J. Raventos, personal communication). In the present investigation, methamphetamine was found to antagonize this block, while adrenaline, noradrenaline, ephedrine and methoxamine were ineffective.

The experiments were performed in twelve mongrel dogs of either sex, weighing between 8 and 17 kg. The animals were anaesthetized with pentobarbitone sodium 35 mg/kg injected intravenously. Blood pressure was recorded from the right carotid artery with a mercury manometer. The right femoral vein was cannulated for injection of the drugs. The heart rate was recorded on an

pranolol by methamphetamine thus appears to be specific. The reversal was always incomplete. The mechanism of this reversal, and the effect of other pressor amines is being investigated.

I thank I.C.I., Ltd., for supplying propranolol ('Inderal').

## PATHOLOGY

## Conjugated Plasma Bilirubin in Jaundice caused by Pigment Overload

WITH overproduction of bilirubin due to haemolytic anaemia, a minor though significant fraction of the plasma bilirubin may exhibit a direct diazo reaction in the absence of detectable liver dysfunction<sup>1</sup>. If the direct-reacting material is in fact conjugated bilirubin<sup>2</sup>, this would support the concept<sup>3</sup> that the secretion of conjugated pigment from the hepatic cell into the bile is a rate limiting step in bilirubin transport across the liver. Chemical identification of this direct-reacting pigment fraction as conjugated bilirubin is difficult, however, because the amounts available for analysis are very small, the extraction procedures are semi-quantitative<sup>4,5</sup> and part of the unconjugated pigment may react directly with the diazo reagent<sup>1,6</sup>.

The appearance of conjugated bilirubin in the plasma was studied in eight intact male Sprague-Dawley rats infused with unconjugated bilirubin at constant rates for 2–12 h. The infused pigment was bound to human albumin or dissolved in murine serum; similar results were obtained with both vehicles. The rates of infusion were selected so that they were below what has been considered the maximal excretory rate for bilirubin in this species<sup>3,7</sup>. Conjugated and unconjugated bilirubin were estimated by the method of Weber and Schalm<sup>8</sup> on blood samples obtained from the tail at hourly intervals. Biliary obstruction as a cause of retention of conjugated bilirubin was investigated with bromsulphophthalein (BSP); 2 h before the end of each experiment 5 mg BSP were injected intravenously and serum samples were analysed at 5, 10, 20, 30 and 45 min thereafter<sup>9</sup>.

Conjugated bilirubin appeared in the plasma within the first hour of infusion, and thereafter the levels of conjugated and total pigment in individual rats remained reasonably constant throughout the experiments (Table 1). In the eight animals the relationship between infused pigment load, total plasma bilirubin and conjugated fraction showed considerable variation (Table 1). In all instances, at least 95 per cent of the injected BSP had disappeared from the plasma in 45 min, indicating unimpaired excretion of the dye<sup>9</sup>.

Table 1. SERUM BILIRUBIN CONCENTRATIONS DURING CONTINUOUS INTRAVENOUS INFUSION OF UNCONJUGATED BILIRUBIN IN RATS

No.	Rate of infusion ( $\mu\text{g}/\text{min}/100\text{ g}$ )	Length of infusion (h)	Serum bilirubin concentrations (mg/100 ml.)		
			Total	Conjugated	Conjugated per cent
1	47	12	12.4 $\pm$ 1.8*	1.6 $\pm$ 0.2*	12.9
2	42	5	10.8 $\pm$ 2.3	1.1 $\pm$ 0.3	10.2
3	40	12	13.8 $\pm$ 1.5	1.2 $\pm$ 0.2	8.7
4	31	7	9.0 $\pm$ 0.8	0.7 $\pm$ 0.2	7.8
5	27	8	10.1 $\pm$ 1.0	0.7 $\pm$ 0.3	6.9
6	23	8	9.9 $\pm$ 0.9	1.3 $\pm$ 0.3	13.1
7	17	9	7.3 $\pm$ 0.7	0.7 $\pm$ 0.1	9.6
8	14	8	3.8 $\pm$ 0.6	0.3 $\pm$ 0.1	7.9

\* Results are expressed as the mean value plus or minus the maximal deviation from the mean for the duration of each experiment.

The polar pigment fraction separated by the method of Weber and Schalm<sup>8</sup> was identified as conjugated bilirubin in the following manner. A rat was infused with <sup>14</sup>C-bilirubin (ref. 10) at a constant rate of 26  $\mu\text{g}/\text{min}/100\text{ g}$  for 2 h and the animal was then exsanguinated. Concentrations of serum <sup>14</sup>C-bilirubin per 100 ml. were: total, 5.9 mg; conjugated<sup>8</sup>, 0.5 mg (that is, 8.4 per cent of total). An aliquot of this serum (2.5 ml.) was given intravenously to a congenitally icteric Gunn rat with an external bile fistula. Gunn rats lack the apparatus for conjugating bilirubin and therefore cannot transfer unconjugated pigment into the bile<sup>11</sup>, but they excrete injected conjugated bilirubin as efficiently as normal rats<sup>3</sup>. During the first hour after injection of the serum, 7.9 per cent of the administered radioactivity was excreted in the bile, and 82 per cent of this label was recovered in <sup>14</sup>C-bilirubin crystallized from this bile sample. By contrast, another

Gunn rat injected with a comparable dose of unconjugated <sup>14</sup>C-bilirubin excreted only 1.3 per cent of the radioactivity in the bile, and most of the label was present in metabolites other than bilirubin<sup>11</sup>.

These findings indicate that with chronic bilirubin overload, the appearance in the plasma of direct-reacting material indeed reflects retention of small amounts of conjugated bilirubin. They further suggest that secretion of conjugated pigment into the bile may become rate-limiting at infusion rates below the maximal excretory capacity of the liver<sup>3,7</sup>.

## Bile Acids on the Skin of Patients with Pruritic Hepatobiliary Disease

CHOLIC and chenodeoxycholic acids are formed from cholesterol in the liver and are then excreted in the bile to the intestinal tract. There they are broken down to form, for example, deoxycholic and lithocholic acids during an enterohepatic circulation<sup>1</sup>.

Bile acids have been implicated in the genesis of pruritus associated with liver disease because: (1) external biliary drainage relieves pruritus in patients with biliary obstruction<sup>2</sup>; (2) the oral administration of ox bile or bile salts increased pruritus in patients with liver disease and caused pruritus to return in those with biliary fistulae<sup>2,3</sup>; (3) Serum bile acids (SBA) are low in normal individuals but are elevated in patients with pruritic hepatobiliary disease<sup>4,5</sup> and elevated in pregnant women with pruritus during the third trimester<sup>6</sup>. (4) The lowering of SBA by cholestyramine, an anion exchange resin which increases the faecal bile acid excretion<sup>7</sup>, is associated with the relief of pruritus in most patients with incomplete biliary obstruction<sup>8–11</sup>.

Bile acids have not been proved to cause pruritus because: (1) external biliary drainage could as well remove other biliary factors which may be responsible for the itching; (2) commercial preparations of bile salts administered have not been pure and feeding of pure cholic acid produced a high SBA without pruritus<sup>6</sup>; (3) all patients with increased SBA do not have pruritus<sup>6,12</sup>; furthermore, the relief of pruritus by norethandrolone could not be correlated with the level of SBA<sup>12</sup>; (4) cholestyramine might remove other factors which may be responsible for pruritus. Also, relief of itching by cholestyramine without a concomitant decrease in SBA has been reported<sup>9</sup>.

Itching is a subjective response to chemical, mechanical, thermal or electrical stimuli acting on nerve fibres in the subepidermal area<sup>13</sup>. If bile acids are related to pruritus they should be present in the area of these sensory nerve endings. There has been no previous report of bile acids on the skin. This communication presents the identifica-

tion by gas liquid chromatography and mass spectrometry and the quantitation by gas liquid chromatography<sup>14</sup> of bile acids on skin.

The skin of the back was swabbed twice over an area of about 25 × 30 cm with cotton wool moistened with distilled acetone. The cotton was then extracted with chloroform/methanol, 1 : 1 (v/v), and the solution filtered. The filtrate was dried *in vacuo* and submitted to a three stage countercurrent distribution between 50 ml. petroleum ether and 50 ml. 70 per cent ethanol. The 70 per cent ethanol extract was dried *in vacuo* and analysed for bile acids.

With or without previous alkaline hydrolysis, the aqueous solution of free bile acids was acidified, extracted with ethyl acetate and methylated with diazomethane. The methylated bile acids were purified on an aluminium oxide (activity grade IV) column, and partial trimethylsilyl ethers and trifluoroacetates were prepared as previously described<sup>14</sup>.

\* Pruritus with excoriations (there were no excoriations on the back).

† 1 month after cholecystojejunostomy and relief of pruritus.

SBR, Serum bilirubin; D, deoxycholic; CD, chenodeoxycholic; and C, cholic acid.

Table 1 shows the retention times relative to methyl deoxycholate of reference standards (as used in previous investigations of this series) and of the peaks on chromatograms of derivatives of the compounds extracted from skin surface. The identifications of deoxycholic, chenodeoxycholic and cholic acids were confirmed by combined

gas liquid chromatography and mass spectrometry, but lithocholic and ursodeoxycholic acids were not positively identified. Bile acids were also found in swabbings of the extremities. In one normal subject and one with pruritus, about 85 per cent of the bile acids on the skin were free (serum bile acids are mostly conjugated)<sup>6,14</sup>.

Table 2 shows the results of the quantitative analyses of the three major bile acids extracted from the skin surface and from serum. In one normal subject, re-extraction of the skin surface immediately after a previous extraction containing 12.3 μg of bile acids yielded no bile acids, but an extraction several days later yielded 8.2 μg. The serum bile acids in normal subjects were as previously reported<sup>14</sup>. Bile acids were not detected on the skin of two additional normal subjects and only deoxycholic acid was seen on the chromatograms from two other controls. Individual bile acids would have been detected if about 0.1 μg were extracted from the skin surface. There were more total bile acids on the skin of the patients with pruritus than on that of normals or of the patients with hepatobiliary disease without pruritus, even when the latter had high SBA. The percentages of individual bile acids on the skin of all subjects were about the same as found in normal serum. Deoxycholic acid, however, was relatively more prominent on the skin than in the serum of patients with hepatobiliary disease (Fig. 1).

Information has not yet been obtained on the secretion and physiological significance of bile acids on the skin. The new finding of bile acids on the skin, however, places them close to the appropriate nerve endings but does not necessarily implicate them in the aetiology of pruritus.

## PHYSIOLOGY

### Relation between the Airborne Diameters of Respiratory Droplets and the Diameter of the Stains left after Recovery

SEVERAL workers have investigated the numbers and sizes of droplets expelled during expiratory manoeuvres such as coughing or sneezing. When droplets are recovered by settling, by impaction or by some form of air sampler, it is necessary to calculate the airborne diameter of the original droplet from the diameter of the stain left after recovery. Duguid<sup>1</sup> repeated the experiments of Strauss<sup>2</sup> in which large droplets of saliva (1–3 mm in diameter) were measured with a micrometer eyepiece, first while they hung from fine glass capillaries and then again after they had fallen, flattened and evaporated on a slide. When a glass slide was used, the diameters of the original droplets were about half those of the stain marks. Buckland and Tyrrell<sup>3</sup>, using glass slides, calculated the airborne diameter of droplets as  $1/2.5$  of the diameter of the stain marks left after impaction. May<sup>4</sup> described the use of glass slides coated with magnesium oxide in estimating the airborne diameter of droplets; droplets landing on this surface will penetrate the magnesium oxide crust like stones falling into snow, and the diameter of the entry-hole is related to the airborne diameter of the droplet. He investigated this relationship for droplets with airborne diameters ranging from  $20\mu$  to  $250\mu$ , determining the airborne diameter by an "absolute method" which involved trapping the droplet in oil, and measuring it microscopically<sup>5</sup>. He concluded that the airborne diameter averaged 0.858 times the magnesium oxide entry-hole diameter, and that this relationship was independent of the speed of impaction and, within the range investigated, of the diameter of the droplet involved.

Slides coated with magnesium oxide are not suitable for use in air samplers, and have other disadvantages in the investigation of droplets originating in the respiratory tract. Investigations undertaken in our laboratories on expulsion of droplets have led us to use a variety of media on which droplets may be recovered by impaction, by settling, and by air sampling, and to investigate the relationship between airborne droplet diameter and the diameter of stains left after recovery.

The vibrating reed aerosol generator<sup>6</sup> produces a stream of droplets of remarkably uniform size. These droplets were allowed to fall on a series of surfaces which were pulled in succession under the stream (Fig. 1). Six types of recovery surface were used: glass slides, glass slides coated thinly with oil, 'Millipore' filter disks (type HA), 5 per cent chloride-free agar gel with 6 per cent silver nitrate, high-grade bond paper, and glass slides coated to a depth of one millimetre with magnesium oxide. The last was used as the reference surface, and was included in each run. The ratio between magnesium oxide entry-hole diameter and stain diameter was found to be the same whether filtered saliva or saline was used to form the aerosol, and saline solution was used for the majority of the experiments. Dye was added to the material used in the vibrating reed aerosol generator to aid in measurement of the stains; in the case of the silver nitrate-agar surface the stain is formed by the precipitate of silver chloride. Droplets with airborne diameters in the range from  $35\mu$  to  $280\mu$  were investigated, and diameters of stains or entry-holes were measured with a micrometer eyepiece, using  $450\times$  magnification.

The droplet stains on clean glass slides and on oiled glass slides were irregular in size and shape, and it was apparent that many of the droplets had shattered on landing or had dried irregularly.

Fig. 1. Vibrating reed aerosol generator and apparatus used to pull various surfaces under stream of uniform droplets.

These surfaces were therefore not considered further. In no case did the diameters of the entry-holes on the magnesium oxide slides vary to a measurable extent during any one run. The diameters of the stains on the three other surfaces ('Millipore' filter disk, silver nitrate-agar gel, and bond paper) were strikingly uniform. Every third droplet stain diameter was measured to a total of twenty measurements; only very rarely did one measurement differ from the others, and then only by one or two microns. The appearances of the entry-holes, and stains are shown in Fig. 2. The relationships between the diameters of the magnesium oxide entry-holes and stain diameters for droplets from the same stream are shown in Table 1 and Fig. 3.

Fig. 2. Appearance of droplet entry-holes on magnesium oxide coated slide (upper left), and of droplet stains on 'Millipore' filter disk (upper right), silver nitrate agar (lower left), and bond paper (lower right). All droplets were from the same stream and measured  $170\mu$  in airborne diameter ( $\times 33$ ).

Fig. 3. Scatter diagram showing relationship between diameter of droplet stains (horizontal axis) and diameter of entry-holes on magnesium oxide coated slide (vertical axis).  $\Delta$ , 'Millipore' filter;  $\circ$ , silver nitrate agar;  $\bullet$ , bond paper.

The relationship between magnesium oxide entry-hole diameter and stain diameter appeared to be linear for these three surfaces over the range of droplet size investigated, and linear regression equations were calculated together with 95 per cent confidence intervals and 95 per cent prediction intervals. Analysis of variance showed that the regression equations were each significant at the 0.1 per cent level ( $P < 0.001$ ) by a considerable margin, and thus that the relationships were in fact linear over the range of diameters investigated. Intercepts on the  $y$  axis were significantly

above the origin for the regression lines for 'Millipore' filter disks and for silver nitrate-agar gel.

The regression equations are:

Magnesium oxide entry-hole diameter = diameter of stain on 'Millipore' filter disk  $\times 0.563 + 13.26\mu$ .

Magnesium oxide entry-hole diameter = diameter of stain on silver nitrate-agar  $\times 0.963 + 27.10\mu$ .

Magnesium oxide entry-hole diameter = diameter of stain on bond paper  $\times 1.017 - 2.78\mu$ .

The 95 per cent confidence intervals and 95 per cent prediction intervals were calculated for the predicted values, and the upper and lower limits of these intervals are shown in Table 2 for the lowest, median and highest predicted values for each of the three recovery media.

## Respiratory Currents of Flatfish

WE have observed specimens of the following species of flatfish (Pleuronectiformes) in an aquarium with a transparent bottom: *Scophthalmus maximus* (L.) (Bothidae); *Limanda limanda* (L.), *Pleuronectes platessa* L. and *Platichthys flesus* (L.) (Pleuronectidae); *Solea solea* (L.) and *Buglossidium luteum* (Risso) (Soleidae). When these fish are resting on the bottom, both opercula move in the manner usual in teleost respiration. When a suspension of carmine in sea water, or ink diluted with sea water, is released from a pipette such that it is drawn into the mouth with the respiratory current, however, it is normally expelled solely through the upper opercular opening (that is, the opercular opening of the ocular side). Hughes<sup>1</sup> thought that a greater volume of water issued from the upper opercular opening than from the lower one of *Pleuronectes* resting on the bottom, but did not find much difference in volume between the two sides. We, however, did not see carmine or ink expelled from the lower opercular opening except when the fish were behaving in an agitated manner.

Our observations suggest that flatfish resting on the bottom pump water over the gills of both sides, but expel it all from the upper opercular opening. This is possible because the opercular cavities communicate ventrally (Fig. 1).

Fig. 1. Diagrammatic median section showing the structures surrounding the channel which connects the opercular cavities of a flatfish. The right side of the figure is ante-ior. b, Basibranchial; s, Inter-branchial septum; u, urohyal.

The urohyal bone is V-shaped, with the angle of the V posterior. The branchiostegal membranes either overlap (for example, *Psettodes*, most Bothidae) or fuse (Pleuronectidae, Soleidae) ventrally. Their posterior edges are folded inwards. They lie inside the V of the urohyal, and enclose a channel connecting the two opercular cavities. We suggest that water pumped through the gills of the blind side passes through this channel to escape through the opercular opening of the ocular side, when the fish is resting on the bottom. We have demonstrated that water can pass through the channel by putting ink in the opercular cavity of the blind side of *Scophthalmus*, *Pleuronectes* and *Solea*, and quickly replacing the fish in the aquarium. Much of the ink is expelled through the opercular opening of the ocular side.

Flatfish spend much of their time in aquaria, and presumably in their natural habitat, resting on the bottom with most of the body covered by sand (see, for instance, ref. 2). Water expelled through the opercular opening of the blind side would then have to percolate through the sand, which might be expected to offer an appreciable resistance to its flow. It would not be impossible to expel water from this side, for the gill openings of *Raia* (Selachii), which often buries itself in sand, are ventral, but it would seem to be disadvantageous.

We have tried to assess the importance of the resistance offered by the sand by experiments with a crude model. The model is a piece of galvanized iron cut to the outline of a *Platichthys* weighing 105 g. A copper tube passes through the model, to which it is soldered, and has a posteriorly directed opening in the position of the siphon of the blind side (the siphon is the small dorsal part of the opercular opening which is not blocked by the in-turned branchiostegal membrane, and through which water can therefore be expelled<sup>3,4</sup>). The internal diameter of the tube is 4 mm. The model is buried about 1 cm below the surface of sand in an aquarium and connected to an aspirator as shown in Fig. 2. Water is added to the aspirator to give a head,  $h$ , of 2.5 cm. The rate of flow of water through the model, as the head fell from 2.5 to 2.0 cm, was found in four experiments to be 30–130 ml./h. A resting fish which weighs 105 g is likely to use at least 2 ml. oxygen/h<sup>5</sup>; it could obtain this by extracting 70 per cent of the dissolved oxygen<sup>5</sup> from 400 ml. of air-saturated water every hour. If the opercular openings were used equally, at least 200 ml. of water should flow through each every hour. The opercula are open for about one third of each cycle<sup>1</sup> so the rate of flow during the part of each cycle when the opercula are open should be about 600 ml./h. Our experiments indicate that such a rate of flow from the lower operculum would require a positive pressure substantially greater than 2 cm water

in the opercular cavity. Hughes<sup>1</sup> found that the maximum positive pressure developed in the opercular cavities of *Pleuronectes* held clear of the bottom was less than 0.5 cm water. It seems likely that the evolution of the channel allowing water to flow from the lower to the upper opercular cavity has substantially reduced the pressure required in the lower cavity during expiration.

In some flatfish the opercular cavities are further connected by a fenestra in the interbranchial septum<sup>6</sup> (the interbranchial septum is shown in Fig. 1). This fenestra probably shares the function of the channel described in this paper. *Lepidorhombus whiffiagonis* (Walbaum) has a large fenestra and a rather small channel.

In *Psettodes belcheri* Bennett the channel described in this paper is poorly developed and may well not be functional. Only a very small ventral portion of each branchiostegal membrane is folded in, and the urohyal is not V-shaped but only slightly emarginate. *Psettodes* is generally agreed to be the most primitive living flatfish<sup>4,7</sup>.

We thank the Museum Nationale d'Histoire Naturelle, Paris, for a specimen of *Psettodes*.

### Inhibition of Membrane Permeability to Chloride by Copper in Molluscan Neurones

Tauc and Gerschenfeld<sup>1</sup> showed that acetylcholine (ACh) iontophoretically injected on the soma of the so-called *H*-neurones of molluscs produces a transient hyperpolarization (ACh potential) and that the inhibitory post-synaptic potentials (IPSP) recorded in these cells were cholinergic.

Kerkut and Thomas<sup>2</sup> investigated the ionic mechanism of the cholinergic IPSP and the ACh-potential in *H*-neurones of *Helix aspersa*. They showed that these potentials are due to an increase in the permeability of the subsynaptic and somatic membranes to chloride and potassium ions. These changes in the ionic permeability result in an influx of chloride and an efflux of potassium. Chloride ions carry about 90 per cent of the current, while the participation of potassium is minimal. These findings were confirmed in *H*-neurones of *Cryptomphallus aspersa*<sup>3</sup>.

When 10<sup>-5</sup> molar copper sulphate is added to the Ringer solution bathing the outer face of the abdominal skin of frogs it produces a dramatic reduction in the permeability to chloride<sup>4,5</sup>. The change in the potential difference between the two faces of the skin is similar to that observed when chloride is replaced in the saline solution bathing the skin by the non-penetrating sulphate ion.

Frog skin has a very complex structure<sup>6</sup> and copper sulphate may act on many possible sites, so that it seemed interesting to see whether copper sulphate has the same effect in a simpler system such as a neuronal membrane. It has been found that copper sulphate practically abolishes the cholinergic IPSP and the ACh potential in snail *H*-neurones and that this effect is due to a reduction of the membrane permeability to chloride.

Neurones from the isolated perioesophageic ganglionic ring of *Cryptomphallus aspersa* were impaled with double-

Fig. 2. The apparatus for the experiment with a model described in the text.

barrelled microelectrodes filled with 0.6 molar potassium sulphate. One of the barrels was connected to a standard direct current set and used to record intracellularly the electrical activity of the neurones, while the other was used, when necessary, to drive the membrane potential to desired levels. ACh was injected iontophoretically on the neuronal perikarya from micropipettes filled with molar ACh iodide, and braking currents were always used to avoid desensitization due to drug leakage<sup>7</sup>. The neurones were bathed with a suitable Ringer solution<sup>8</sup> to which copper sulphate was added to give a final concentration of  $10^{-4}$  moles/l. A total of eleven *H*-neurones were examined.

The changes observed in the cholinergic IPSP after adding copper sulphate to the Ringer solution are illustrated in Fig. 1A. A control IPSP is shown in A1 while those recorded 4, 8 and 15 min after the addition of copper sulphate are shown in A2, A3 and A4, respectively. It can be seen that the IPSP became reduced to 20 per cent of its original amplitude. On the other hand, Fig. 1B shows that copper sulphate fails to reduce (B2-4) the non-cholinergic IPSP present in other cells of the same nervous system<sup>9</sup>, which are solely due to an increase in the potassium permeability of the subsynaptic membrane<sup>10</sup>.

The *H*-neurones examined had resting potentials ranging from  $-40$  to  $-50$  mV and were depolarized by 4–5 mV on addition of copper sulphate. Only in one case was a transient hyperpolarization of 5 mV observed. In some cells an increase in the synaptic noise was recorded which coincided with the depolarization.

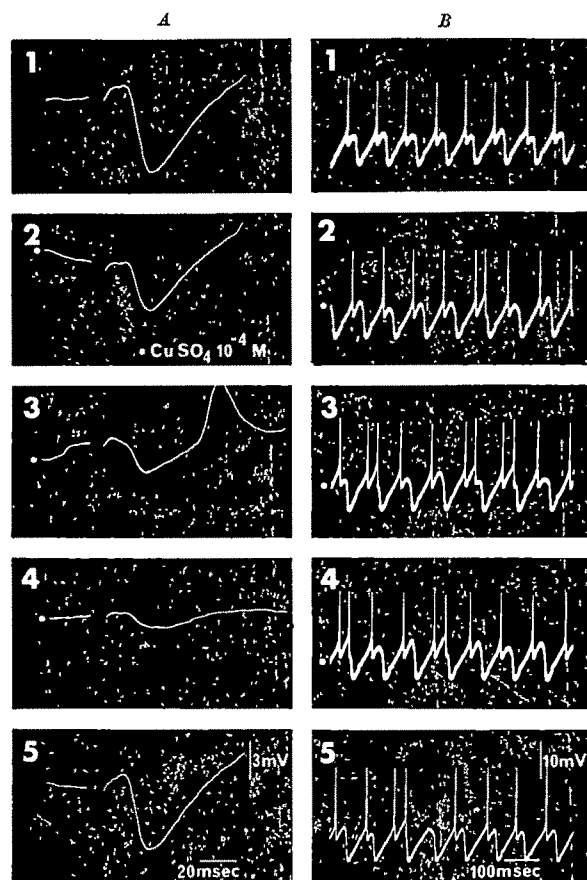

Fig. 1. A, Intracellular recording from an *H*-neurone showing the effect of  $10^{-4}$  molar copper sulphate on a cholinergic IPSP evoked by electrical stimulation. A1, Control cholinergic IPSP. A2–A4, The same IPSP 4, 8 and 15 min after the copper sulphate was added. A5, The cholinergic IPSP recovered after prolonged washing with snail Ringer solution. In B, recording from a neurone with potassium-dependent non-cholinergic IPSP (the upper part of the spikes is not shown in the records). B1, Spontaneous non-cholinergic IPSPs intermingled with spikes before addition of copper sulphate. B2–B4, The same activity 5, 10 and 20 min after adding copper sulphate; B5, wash.

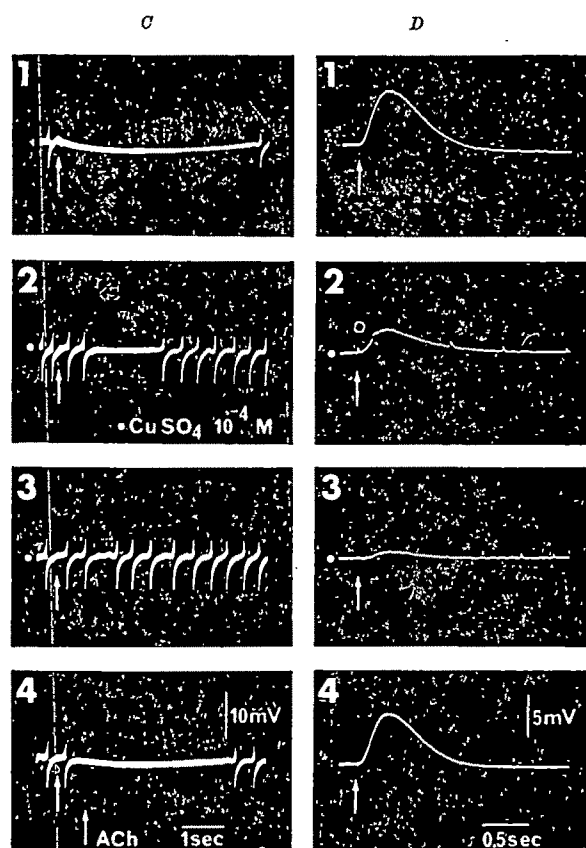

Fig. 2. Effect of  $10^{-4}$  molar copper sulphate on ACh potentials in *H*-neurones (injections at arrows). C, Effect on the hyperpolarizing response (the upper part of the spikes is not shown in records). C1, Control ACh potential. C2, 2 min, and C3, 6 min after copper sulphate was added. C4, Effect of ACh is recovered after washing the preparation. In D, reversed ACh potential by hyperpolarizing the neurone (see text). D1, Control injection. D2, 1 min, and D3, 4 min after adding copper sulphate. D4, Recovery of the depolarizing effect of ACh after washing.

Fig. 2C shows that copper sulphate is also active on the ACh potential: 6 min after adding copper sulphate to the Ringer solution the ACh potential is practically abolished (compare C3 with C1).

When the resting potential of an *H*-neurone is artificially increased beyond the inversion level of the ACh potential ( $E_{ACh}$ ), the latter is reversed and becomes depolarizing<sup>1</sup>. Fig. 2D corresponds with this situation in an *H*-neurone with a measured  $E_{ACh}$  of  $-55$  mV, in which the membrane potential was driven by passing inward current from the resting level of  $-48$  mV to  $-85$  mV. In these conditions copper sulphate also blocks the reversed ACh potential (D2 and D3). The effect of copper sulphate on ACh injections is faster than on the cholinergic IPSP, and the maximal effect on ACh potential is attained in 4–7 min. This agrees with the fact that the naked neuronal soma is in direct contact with the saline solution containing copper sulphate, while the synapses are more deeply located in the ganglion neuropile at a certain distance from the soma<sup>11</sup>.

In practically all cells the effect of copper sulphate was reversible, and the amplitude of the IPSP, the ACh potential and the resting potential recovered after prolonged washing in snail Ringer solution (Fig. 1, A5; and Fig. 2, C4 and D4).

No effect of copper sulphate on the membrane resistance was observed when square pulses were passed across the neuronal membrane. Because copper sulphate has no effect on the membrane resistance, it can be assumed that it reduces the increased permeabilities to chloride and potassium ions elicited by ACh both at the somatic and synaptic regions of *H*-neurones. The participa-

tion of potassium in the mechanism generating the cholinergic IPSP and ACh potential is minimal, so that a fall in potassium permeability after administration of copper sulphate cannot by itself explain the present results. Furthermore, the absence of action of copper sulphate on neurones with non-cholinergic IPSPs which depend on potassium excludes an effect on potassium permeability. It may be then concluded that, as in the case of frog skin, copper sulphate in dilute concentrations markedly reduces the permeability of the neuronal membrane to chloride. The effect seems to be similar for the fluxes of chloride in both directions, because the hyperpolarizing and the depolarizing effects of ACh are reduced in the same proportion. This indicates that the effect of copper sulphate is not achieved through a modification of the chloride pump which probably exists in these cells<sup>2</sup>.

According to the Goldman-Hodgkin-Katz equation, copper sulphate should produce an increase in the resting potential by reducing the permeability to chloride. The fact that copper sulphate produces a diminution of the resting potential is rather puzzling, but further work is needed to elucidate this point.

We thank Dr. M. Cerejido for reading the manuscript. This work was supported by grants from the Consejo Nacional de Investigaciones Científicas y Técnicas, Argentina, and the U.S. Air Force Office of Scientific Research.

### Alterations in the Urinary Excretion of Pseudouridine and Deoxycytidine in Rats Induced by Glucocorticoids

ONE of the characteristics of corticoid action<sup>1-5</sup> is a marked catabolic effect on the lymphatic organs, such as thymus and spleen. This is demonstrated by the loss in weight of these organs<sup>6,7</sup> as well as by the decrease in the nucleic acid content<sup>7</sup>, and by the diminution of incorporation of the precursors of nucleic acids after administration of glucocorticoids<sup>8</sup>.

Degradation of nucleic acids is accompanied by an increased excretion of their catabolic products (pseudouridine and deoxycytidine) in urine<sup>9-11</sup>; this has been proved by the effect of ionizing radiation on the organism. The object of the present work was to ascertain whether the catabolic effect of corticoids on the nucleic acids in the spleen results in a similar degradation pathway.

Infantile male rats of the Wistar-Konárovics strain, weighing 55-65 g, in groups of five, were kept in metabolic cages and fed on a standard diet. Urine was collected every 24 h. Pseudouridine and deoxycytidine were determined in the urine using a method previously

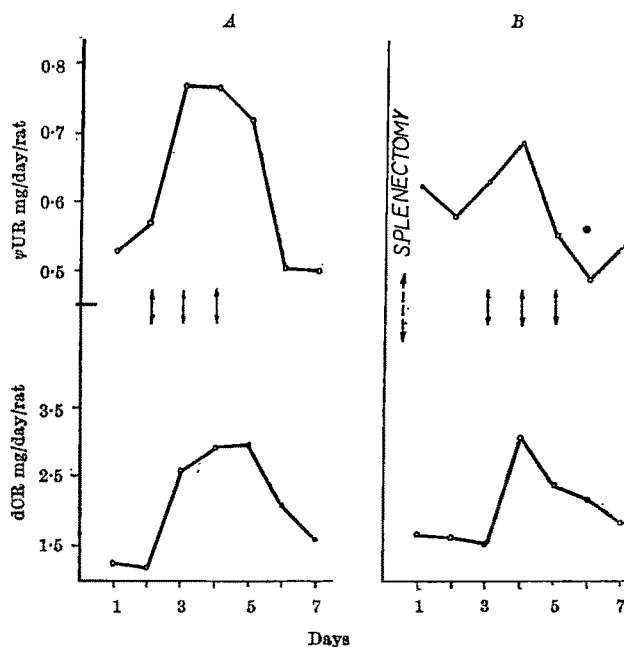

Fig. 1. The concentration of deoxycytidine (dCR) and pseudouridine (pUR) in the urine of eusplenic (A) and splenectomized (B) rats after administration of cortisone.

described<sup>10</sup>. Splenectomy was performed under ether anaesthesia 4 days before the administration of cortisone. In both splenectomized and normal animals cortisone was given in a dose of 2 mg/100 g of body weight for 3 consecutive days.

In normal rats cortisone produced a marked increase in the excretion of both catabolites 24 h after the first administration. This increase was maintained after the repeated administration of the steroid but ceased rapidly after the last dose (Fig. 1A). In splenectomized animals the course of the urinary excretion of these catabolites differed considerably after the administration of cortisone, in comparison with the findings in the normal animals. In this experiment the increase in their content occurred after the first dose only; repeated administration did not produce any effect (Fig. 1B).

On the basis of these experiments it may be assumed that the mode of catabolic degradation of nucleic acids is similar after both ionizing radiation<sup>9-11</sup> and glucocorticoid action in that in both cases degradation of nucleic acids takes place predominantly in the spleen.

## Asymmetric Distribution of Materials sloughed by Hamster Intestinal Sacs

EVERTED sacs of the small intestine have been used widely for the investigation of transport and metabolism by the small intestine<sup>1</sup>. When such sacs are incubated with a buffer, they slough materials which can interfere with the assay of compounds being investigated and suitable corrections become necessary<sup>2</sup>. Despite this, there have not been any reports as to the nature and distribution of the liberated substances. The present communication gives preliminary data concerning the composition of some of these materials and emphasizes that their distribution is quite asymmetric.

Everted intestinal sacs were prepared from adult golden hamsters (*Mesocricetus auratus*) of both sexes. The animals were allowed food and water freely until they were killed. The small intestine was removed, washed with Krebs-bicarbonate buffer pH 7.4, and then everted. Three sacs were made from each small intestine. Individual sacs were filled with 1 ml. of buffer (serosal fluid) and placed in a 25 ml. flask containing 5 ml. of identical buffer (mucosal fluid). After gassing with 95 per cent oxygen (O<sub>2</sub>) + 5 per cent carbon dioxide (CO<sub>2</sub>), the flasks were stoppered and incubated at 37° C for 1 h. The fluids were drained and centrifuged at full speed in a centrifuge for 20 min in order to remove sloughed tissue. The mucosal and serosal solutions were then handled identically, but separately.

When run at a 1:31 dilution (with pH 7.4 Krebs-bicarbonate buffer), the average optical densities of the fluids (six sacs) were as shown in Table 1.

Table 1  
Serosal solution    Mucosal solution

260 mμ	0.18	0.07
280 mμ	0.12	0.07

It might be expected that the mucosal side would have a higher concentration of sloughed substances, since the mucosal cells tend to disintegrate histologically during incubation. Yet the optical density was higher in the serosal solution. In terms of total amount, since there was five times as much serosal as mucosal fluid, the mucosal solution contained about two-thirds of the quality of 280 mμ absorbing materials present in both fluids.

One-tenth millilitre of each liquid was dried at 105° C and treated with 3.0 ml. of 0.1 per cent ninhydrin in glacial acetic acid<sup>2</sup>. After 30 min, the optical density was read at 440 mμ. The average of the serosal solutions was 0.62, while the average of the mucosal liquids was 0.19. There was thus a concentration of ninhydrin-reacting materials within the sacs more than three times greater than that in the mucosal fluid.

Following ascending chromatography on Whatman No. 1 paper, strips were air dried and sprayed with 0.1 per cent ninhydrin in butanol. The strips were visually inspected 1 h later, following 2 min of heating at 105° C. Corresponding spots were observed in both mucosal and serosal solutions; there was a much greater intensity of colour with the serosal fluids.

Lipids in mucosal and serosal solutions were also extracted (one part to nine parts of 2:1 chloroform-

methanol) and spotted on glass plates that had been coated with 250μ of activated 'Absorbosil-1'. Thin layer chromatography was performed in a solvent system of petroleum ether (boiling point 30°-60°): diethyl ether (peroxide free): glacial acetic acid, 90:10:1. After 45 min the plates were air-dried and stained with iodine vapour. Spots were outlined with a pencil and a tracing made. Diglycerides, cholesterol, unsaturated fatty acids, saturated fatty acids, triglycerides and cholesterol esters were identified by their *R<sub>F</sub>* values (and comparison with standards). As judged by the intensity of the iodine stain, serosal fluids contained less triglyceride than the mucosal solution. The serosal fluid, however, appeared to contain more fatty acid. This suggests that triglycerides were being split by the intestinal sacs, with fatty acids then entering the serosal fluid.

Aliquots of the lipid extracts were evaporated at 4° C and an aliquot was transmethylated for 6 h at reflux temperature using 5 per cent sulphuric acid in anhydrous methanol. The fatty acid composition was analysed by using the resultant methyl esters and gas-liquid chromatography (see Table 3). Peaks were compared with known standards. The composition of the large "unknown" peak from the serosal fluid is uncertain. Its retention time on the chromatographic column was 4.8 times that of stearic acid and may represent oxidized fatty acids.

Table 3

Fatty acid	Mucosa (per cent)	Serosa (per cent)
14:0	3.2	2.2
16:0	20.6	17.2
16:1	3.9	4.0
18:0	10.9	7.2
18:1	24.2	14.8
18:2	23.1	12.1
18:3	3.2	3.6
20:0	—	1.7
20:4	1.8	1.4
Unknown	9.0	35.7

Asymmetric distribution of materials sloughed by intestinal sacs *in vitro* may be a manifestation of continuing transport from the mucosal surface toward the serosal surface. In addition, any persistent electrical potential difference across the sacs (mucosa negative with respect to the serosa) would also contribute to an asymmetry of the materials.

## Influence of the Oviduct and Ovum on Cyclic Ovarian Activity in the Rat

THE muscular and secretory activity of the female genital tract has been implicated in the processes of gamete transport with emphasis on the role of the uterus and oviduct. It is well known that the physiological activity of these two portions of the female genital tract varies with respect to the hormonal phases of the ovarian cycle<sup>1</sup>. The ampullary portion of the oviduct plays still another important part as the site of fertilization in most mammals. In spite of the wealth of information concerning mechanisms of tubal transport, there has been a lack of knowledge concerning any additional interactions between the oviduct and ovary. It has been reported by Bishop<sup>2</sup> that secretions of the oviduct undergo changes in response to cyclic ovarian activity.

One major characteristic of mammalian ovarian cycles is the shedding of the ovum at the time of ovulation, and these ova, whether fertilized or not, are transported into

Table 2

Solvent system	<i>R<sub>F</sub></i> values of principal ninhydrin-reacting spots

Table 1. EFFECTS OF OVIDUCT LIGATION AND EXTIRPATION ON CYCLIC OVARIAN ACTIVITY

Experimental group	No. animals	Pre-operative cycles (days)			Post-operative cycles (days)		
		No.	Range	Average	No.	Range	Average
(I) Sham operated	8	13	4-6	4.6	42	4-7	4.5
(II) Ligation utero-tubal junction	8	14	4-6	5.1	37	4-9	5.4
(III) Ligation ovarian end oviduct	7	22	3-6	4.4	36	4-9	4.6
(IV) Removal both oviducts	7	22	4-7	4.4	41	4-6	4.3

the uterus. Normally, the uterine environment is essential for implantation; however, in some instances the blastocyst may implant and develop within the oviduct as evidenced by tubal ectopic pregnancies in humans<sup>2</sup>. Scientific investigation has not shown if the transport of the unfertilized ovum and/or oviduct secretions into the uterus influence cyclic ovarian activity. It was the purpose of this investigation to determine if there existed any interrelationships between the oviduct and/or ovum and ovarian activity.

Mature female rats were divided into four experimental groups: sham-operated controls (I), those with permanent ligatures at the utero-tubal junction (II), those with permanent ligatures at the ovarian end of the oviducts (III) and rats in which both oviducts were removed (IV). The operations were performed under ether anaesthesia with the aid of a dissecting microscope. Daily vaginal smears were examined as the criterion for ovarian activity before and following surgical treatment.

The results of this preliminary investigation are shown in Table 1. The seventy-one pre-operative vaginal cycles were characterized by a range of 3-7 days in length and an average of 4.6 days. The one hundred and fifty-six post-surgical cycles showed a range of 4-9 days and an average length of 4.7 days. A statistical analysis of the data revealed no significant difference among the different experimental groups or between the pre- and post-operative cycles of each group.

It would appear that the presence of the ovum in the oviduct and uterus does not influence cyclic ovarian activity in rats as evidenced by females with permanent ligatures at the ovarian end of the oviduct and those with ligatures at the utero-tubal junction (groups II and III). It was also interesting to note that surgical opening of the ovarian bursa (essential for ligation of oviduct at ovarian end) did not appear to alter the vaginal cycles. In addition, five of the eight females in group II were characterized by fluid-filled bursal cysts on one or both ovaries at post-mortem examination, which indicates that there is a constant influx of oviduct secretions into the uterus. It would therefore appear that the oviducts are not essential for cyclic ovarian activity in the rat as evidenced by the removal of both oviducts in group IV. This would be in agreement with data obtained from women with a bilateral tubal ligation or bilateral salpingectomy who appear to have normal menstrual cycles, provided the surgical procedures have not impaired the ovarian blood supply.

These preliminary studies would suggest that the physiological activity of the oviducts is concerned primarily with gamete transport and fertilization mechanisms rather than the regulation of cyclic ovarian activity. It would also appear that the unfertilized ovum plays no part in the sequential aspects of the ovarian cycle. On the other hand, the present studies did not determine the long term effects of tubal ligation or bilateral extirpation of the oviducts on the cyclic ovarian activity of the rat.

## RADIOBIOLOGY

### Chromosomal Alterations in Pearl Millet induced by $\gamma$ -Rays

To investigate the effect of  $\gamma$ -ray irradiation on *B* chromosomes, dry seeds of a stock of *Pennisetum typhoides* carrying *B* chromosomes were exposed to  $\gamma$ -ray irradiation in doses of 10 kr., 20 kr. and 30 kr.; the  $\gamma$ -ray source was cobalt-60. The treated seeds were sown in pots and those that survived were transplanted into the field later. Meiosis in the pollen mother cells was examined to determine the types of aberration produced. For cytological investigation young spikelets were fixed in acetic alcohol (in proportions of 1:4) and anther squashes were made in acetocarmine.

The most common aberration was a ring or chain of four chromosomes. When the chromosomes concerned with the organization of the nucleolus were involved in the translocations, a chain of four would form at first metaphase because chiasma formation is very rare in the satellited short arms of these chromosomes. The number of *B* chromosomes varied from three to five in these cells and they showed regular associations into trivalents when three *B* chromosomes were present; one quadrivalent or two bivalents or a trivalent and a univalent when four *B* chromosomes were present, and a trivalent and a bivalent when five *B* chromosomes were present.

An aberration resulting in the formation of a chain of six and four bivalents was rare and was observed in only one plant grown from seed exposed to 30 kr. Here the chromosomes with nucleolus organizers were involved and so only a chain of six occurs at first metaphase. The *B* chromosomes in these cells with chains of six showed the usual variability in number, from three to five in each cell. Regular pairing was observed among these *B* chromosomes to give rise to higher associations like trivalents and quadrivalents.

More complicated types of configurations of *A* chromosomes were encountered in one plant raised from seed exposed to 30 kr. This plant has fifteen *A* chromosomes instead of the usual fourteen, and a variable number of *B* chromosomes. The more frequent type of configuration was a chain of seven chromosomes and four bivalents (Fig. 1). Here also the chromosomes concerned with organization of the nucleolus were involved. In a few cases the extra chromosome was associated with one of the chromosomes of a chain of six to give an association of seven (Fig. 2). In two cells a chain of three, a ring of three and four bivalents and a univalent were observed (Fig. 3). The univalent was lying on the nucleolus but it was difficult to say whether it possessed a nucleolus organizer or not. In another cell was a ring of three and six bivalents. In all these cells with fifteen *A* chromosomes two dot-like fragments with a diameter less than that of the *A* chromosomes were observed regularly to be present. These fragments underwent regular first anaphase segregation and several times one of these divided and the two halves moved to the poles (arrowed in Fig. 4). The fragments regularly appeared during second division of meiosis. These facts, together with the fact that they passed through several cell generations to reach the pollen mother cell stage, show that they are centric fragments.

The *B* chromosomes paired normally in these cells with fifteen chromosomes; congression in first metaphase and segregation in first anaphase were also normal. Non-disjunction at first anaphase which was frequent in untreated material was not, however, observed here.

The effect of X-ray irradiation in *Pennisetum typhoides* has been investigated<sup>1</sup>. Dry seed was given a dose of 42,000 r. for 1 h, 2 h and 3 h. In the plants raised from these seeds there were rings of four, rings of six, two rings of four, rings of eight and rings of three along with a short fourth segment. Inversion was suggested by the presence of bridges at first anaphase. Aneuploidy and fragments

Figs. 1-4.

have not been reported. From a comparison of the results it is apparent that the types of chromosomal aberrations induced by X-rays and  $\gamma$ -rays to a large extent are alike.

Extra chromosomes have been reported by Caldecott and Smith<sup>2</sup> in plants grown from barley seed previously subjected to X-ray irradiation. In one spikelet they observed a single isochromosome and a total of fifteen chromosomes in a cell instead of the usual fourteen. The increase in number, according to them, is the consequence of the formation of an isochromosome. In the present material there is an indication that the extra chromosome might be an isochromosome, because a ring of three was observed in two cells. The presence of an isochromosome also explains the formation of a ring of seven.

The seeds were irradiated at the Biology Division of the Atomic Energy Establishment of Bombay. I thank Professor J. Venkateswarlu of Andhra University for

facilities and encouragement. I also thank Mr. M. Krishna Rao of this Department for the microphotographs.

## BIOLOGY

### Resistance to Cold in *Ceratomia catalpae*

SALT<sup>1</sup> has reported resistance to frost and to being frozen in several species of arthropods. He has also reported on the synthesis and accumulation of a low molecular weight solute (glycerol) in insects and has suggested that this may explain resistance to cold<sup>2</sup>. Lozina-Lozinsky<sup>3</sup> stated that in the caterpillar, *Pyrausta nubilalis*, which can tolerate extremely low temperatures, the proteins and nucleoproteins can resist an increase in concentrations of the electrolytes. Asahina and Tanno<sup>4</sup> found that the overwintering pre-pupal larvae of a sawfly, *Trichiocampus populi*, were able to survive freezing at  $-30^{\circ}\text{C}$  for a full day, and withstand liquid nitrogen temperature ( $-195.8^{\circ}\text{C}$ ) provided they had been previously frozen at temperatures lower than  $-20^{\circ}\text{C}$ .

Work in our laboratories has demonstrated freeze resistance in the larvae of the large American hawk moth, *Ceratomia catalpae*. Seven groups of ten larvae were cooled to  $+4^{\circ}\text{C}$  for 21 days. During this period there was no apparent change in diapause. When brought to room temperature, they began to move and feed in a normal fashion. All survived to the pupal stage (about 72 h). In a group of thirty that were precooled to  $+4^{\circ}\text{C}$  for 6 h and then taken to  $-20^{\circ}\text{C}$  for 12 h, sixteen survived and went on to pupal stage. A further group of thirty was precooled to  $+4^{\circ}\text{C}$  for 6 h, frozen at  $-20^{\circ}\text{C}$  for 12 h and then immersed in liquid nitrogen ( $-195.8^{\circ}\text{C}$ ) for 5 min. After allowing this group to remain at room temperature for 15 h, movement was recorded in only two individuals. In the final group of fifty larvae taken to  $+4^{\circ}\text{C}$  for sixty-four days, forty-six survived and went on to pupae. All individuals remained in diapause while at these temperatures.

### Occurrence of *Teleonemia scrupulosa* on *Sesamum indicum* Linn. in Uganda

*Teleonemia scrupulosa* (Stål) (Hemiptera, Tingidae) is a native of the tropical regions of the Americas and has been extensively used as an agent for the biological control of the noxious weed *Lantana camara* Linn. (Verbenaceae). It was introduced first into Hawaii<sup>1</sup>; since then it has been introduced into Fiji<sup>2</sup>, Australia<sup>3</sup>, Indonesia<sup>4</sup> and other island groups in the Pacific. It is also established in India<sup>5</sup>, Mauritius, and South<sup>6</sup>, Central<sup>7</sup> and East Africa. In general the level of control achieved in these areas has

been disappointing, although severe local defoliation and partial control has been reported from many of these countries, and it is generally considered to be a useful addition to the insect complex used in the control of *Lantana*. Exhaustive tests in Fiji and Australia showed that this Tingid would feed on none of the plants tested except *Lantana*<sup>8</sup>. The bug was reported in Texas on *Callirhoe involucrata* (Malvaceae) and a plant of the mint family but was unable to breed or live long on them<sup>9</sup>. Its release in India was not recommended because laboratory tests showed that it could feed on teak (*Tectona grandis* Linn.) which is also a member of the Verbenaceae although breeding was slow and *Lantana* was preferred<sup>10</sup>. When it escaped at Dehra Dun, however, it became established on *Lantana* but could not be found on nearby teak<sup>5</sup>. The only other previous records of attack by *T. scrupulosa* on other plants are its occurrence on *Myoporum sandwicense* (Myoporaceae) and species of *Xanthium* (Compositae) in Hawaii, ebony in the United States, and *Lippia alba* (Verbenaceae) in the Antilles, according to the catalogue just published, which includes some hitherto overlooked records<sup>11</sup>.

*T. scrupulosa* (the lacebug) was first introduced into East Africa in 1952, from Hawaii, and was released on the Kenya Coast in 1953, where it became established<sup>12</sup>. Successful releases were made later at Nairobi and near Kisumu in Kenya, Zanzibar, Dar-es-Salaam and Morogoro in Tanzania, and in Uganda at Kawanda Research Station in 1960. In the mistaken belief that it had not become established at Kawanda, fresh material from Trinidad was also released there in 1962. In all these places its effect on *Lantana* conformed with that found previously and there have been no reports of its occurrence on crop plants. When adults collected from Kawanda were released at Serere Research Station in June 1963, severe defoliation around the release point to a distance of several hundred yards was caused in the dry season from November 1963 to March 1964. With the onset of the rains in April 1964 considerable regrowth and foliage production was observed and flowers developed. In the dry season of 1964-65 there was a massive population build-up of *T. scrupulosa* which was not followed by the expected regrowth of *Lantana* at the onset of the rains. New shoots and flowers were immediately attacked and defoliation around Serere Research Station was almost complete for a radius of 2-3 miles by the end of May 1965. By this time the lacebug had spread naturally over a wide area and has been recovered 18 miles from the place of release.

A disconcerting feature was the discovery of numbers of the insect on cultivated *Sesamum indicum* Linn. (Pedaliaceae) on the Research Station in early May and again on an experimental block planted in July 1965. The population on *Sesamum* increased until five to ten insects were present on each leaf. In addition, stems, flowers and nectaries were attacked. Copulation and oviposition were observed on *Sesamum*. Large numbers of eggs were laid, and viable nymphs emerged. Mortality of nymphs was high, but the insect was able to complete the cycle from egg to adult on *Sesamum*.

So far it has not been possible to carry out controlled experiments, but the following, largely qualitative, observations have been made. On *Sesamum* the bionomics of the insect were similar to those on *Lantana*<sup>8</sup>. The eggs were laid on the mid-rib or main leaf veins on the under surface of leaves, and caused severe necrosis. Up to twenty eggs were laid on one vein, and they frequently caused severe distortion around the point of insertion. Nymphs fed on the undersurface of leaves and were gregarious. Development was slower on *Sesamum* than on *Lantana*. A high proportion of nymphs bred on *Sesamum* failed to complete the final ecdysis successfully. The young adults died attached to the old cuticle. Approximately one hundred late instar nymphs collected from *Sesamum* in the field were caged in the laboratory on excised *Sesamum* leaves. From these, only twelve adults

were obtained; their emergence was staggered and none laid any eggs.

Defoliation occurred on plants severely attacked by the bug. A block of *Sesamum*, sprayed with dimethoate to control gall midge, *Asphondylia sesami* Felt., was clearly far less damaged than an adjacent block of the same crop deliberately left unsprayed. Far fewer capsules were produced on *Sesamum* which was attacked by *T. scrupulosa*.

These observations are of considerable importance in that *T. scrupulosa* is known to feed on few plants other than *Lantana camara* and allied species of the genus. It is also of interest that, though *Sesamum* is also grown in many of the countries where *T. scrupulosa* now occurs (for example, Mexico, Java, Kenya), no previous records of its occurrence on *Sesamum* can be traced. It has also been found feeding, but not ovipositing, on the wild *Sesamum angustifolium* Oliv. and on young silks of maize at Serere, and at Kawanda a few adults have been found on *Sesamum indicum*. It is as yet too early to predict the final outcome, but it seems likely that *T. scrupulosa* will be able to control *Lantana* in the Serere area.

The very poor survival rate of nymphs on *Sesamum*, and the fact that it is an annual crop in the ground for only 4 months, suggest that there is little danger of the development of a strain which is adapted to *Sesamum*. When the present overpopulation has subsided so that production of adults is in balance with the quantity of *Lantana* available and there is no great surplus of adult bugs unable to feed on their normal host, movement on to *Sesamum*, if it occurs, will be slight. Because the plant is available as a host for only a portion of each year, and because it is grown at the season least favourable to *T. scrupulosa*, it would then be unlikely that any adults which find it would be able to build up a damaging population.

### Vitamin B<sub>12</sub>-controlled Biotin Avidity in Autotrophic *Euglena gracilis*

SEVERAL years ago, it was found that cells from recently isolated but impure (0.1 per cent contaminants) cultures of the autotrophic bacterium *Nitrosomonas europaea* contained more than 10 µg biotin/g dried cells<sup>1</sup>. Because such values are considerably higher than the 1.7-7.1 µg biotin per g of dried cells reported for five species of heterotrophic bacteria<sup>2</sup>, we suggested that autotrophs might require large amounts of biotin for utilization of their carbon source, carbon dioxide. Assay of biotin content of pure cultures of autotrophic bacteria revealed that they contained the same amount or only slightly less biotin than do heterotrophs: *N. europaea*

contained 1.6–2.4  $\mu\text{g}$  and *Nitrobacter agilis* contained 0.56–1.0  $\mu\text{g}$  biotin/g dried cells<sup>2</sup>.

We then revised our speculation to consider biotin uptake associated with biotin content of autotrophic cells. In other words, if biotin is essential for autotrophic life, then does an autotroph such as *N. agilis* with low biotin content take up more biotin than *N. europaea* which actually contains about twice as much biotin? The experimental test of this question showed that  $1 \times 10^8$  *N. agilis* cells took up and utilized 150  $\mu\text{g}$  of biotin while  $1 \times 10^8$  *N. europaea* cells did not take up detectable amounts of the vitamin<sup>3</sup>.

A more suitable tool for investigation of biotin avidity is an organism which can be cultivated both autotrophically and heterotrophically and which does not require biotin for growth. *Euglena gracilis* meets these requirements and was therefore used for the investigations on cellular biotin content and uptake presented in this report.

*Euglena gracilis*, Z strain, was grown in an autotrophic medium<sup>4</sup> containing either minimal (0.1  $\mu\text{g}/\text{ml}$ .) or sufficient (1.0  $\mu\text{g}/\text{ml}$ .) vitamin B<sub>12</sub> or in one of two heterotrophic media, either the autotrophic medium supplemented with glucose (10  $\text{mg}/\text{ml}$ .), glycolic acid (0.5  $\text{mg}/\text{ml}$ .) and excess vitamin B<sub>12</sub> (5.0  $\mu\text{g}/\text{ml}$ .), or Difco-Bacto 0532 *Euglena* B<sub>12</sub> assay medium<sup>5</sup> containing either minimal or sufficient vitamin B<sub>12</sub>. In all experiments 50 ml. cultures were grown in acid-washed 125 Erlenmeyer flasks with turbulence maintained by bubbling ordinary air through the cultures at the rate of 60 bubbles/min. Cultures were grown under constant illumination with warm white fluorescent lights at 24–26° C until the cultures were well into their exponential growth phase. With an inoculum of about 500–600 cells/culture, total incubation time took about one week.

To assay biotin content of cells, log phase cells were collected by centrifugation, washed, lyophilized, and stored in a cool, dark cabinet until the time of assay for biotin content. Free biotin content was measured in aliquots of suspended cell material, and free plus bound biotin content by hydrolysing 100–200  $\text{mg}$  of lyophilized cells in 6 N sulphuric acid, according to the method of Skeggs<sup>6</sup>. The hydrolysate was then neutralized to pH 6.5–7.0, added to the biotin assay medium, and assayed using the *Lactobacillus plantarum* method<sup>4</sup>. Bound biotin content was calculated as the difference between total and free biotin.

To measure biotin uptake, log phase cells were counted with a haemocytometer, centrifuged, and resuspended in a portion of their original medium so that there were  $3\text{--}8 \times 10^6$  cells/ml. Biotin, at a final concentration of 150  $\mu\text{g}/\text{ml}$ ., was offered aseptically to these cell suspensions and, except for a small sample of suspension immediately removed for assay purposes (zero time control), were incubated for 3 h under the same conditions which served for growth. A 3 h period is much less than the time required for one cell division of *E. gracilis*. Supernatants from both the zero time control and the 3 h incubations were separated from the cells by centrifugation, and aliquots of these supernatants assayed microbiologically<sup>4</sup> for biotin content.

The results from assay of our zero time controls showed that our assay was accurate to about  $\pm 5$  per cent, and that no biotin was produced by any cultures before addition of biotin. The amounts of biotin found in *euglena* cells grown with sufficient vitamin B<sub>12</sub> and grown under a variety of conditions are given in Table 1. Total biotin content was remarkably constant under all conditions tested.

Data of the biotin uptake experiments (Table 2) showed that the autotrophic, B<sub>12</sub>-sufficient *euglena* cells took up to 6  $\mu\text{g}$  of biotin/ $3.3 \times 10^6$  cells, while the autotrophic, B<sub>12</sub>-deficient and all the heterotrophic cells (regardless of conditions of their B<sub>12</sub> nutrition) did not take up detectable amounts of biotin. These results, which show vitamin

B<sub>12</sub> control of biotin uptake in autotrophically grown *Euglena*, can be interpreted as an example of metabolic homeostasis at the coenzyme level. Some biotin-enzyme catalysed and B<sub>12</sub> enzyme-catalysed reactions are closely associated metabolically, for example, in the formation of propionate from succinate<sup>7</sup>. With limitation of B<sub>12</sub>-reactions, as in B<sub>12</sub>-deficiency caused by supplying only minimal amounts of the vitamin, endogenous biotin suffices; but with B<sub>12</sub> in excess, the endogenous biotin supply now becomes the metabolic limiter and the cells show avidity for exogenous biotin (Table 2). Such limitation becomes critical for autotrophically grown *Euglena* where carbon dioxide fixation is the prime source of cellular carbon.

Table 1. BIOTIN CONTENT/G DRY WEIGHT OF CELLS OF *Euglena gracilis* GROWN IN THE ABSENCE OF EXOGENOUS BIOTIN

Growth medium	Grown in light			Grown in dark

Table 2. BIOTIN UPTAKE BY *Euglena gracilis*, GROWN IN THE LIGHT IN THE ABSENCE OF EXOGENOUS BIOTIN

Growth conditions	Vitamin B <sub>12</sub> in medium ( $\mu\text{g}$ per cent)	Cells/ml. suspended in biotin containing medium	$\mu\text{g}$ biotin* taken up/ml./3 h
Autotrophic medium I	10	$8 \times 10^6$	0†
	100	$3.3 \times 10^6$	6
Heterotrophic medium ‡	10	$3.5 \times 10^6$	0†
	100	$3.6 \times 10^6$	0†

\* As described by assay with *Lactobacillus plantarum*<sup>4</sup>.

† Less than 0.1  $\mu\text{g}$ .

‡ As described by Guttman<sup>5</sup>.

At least one carbon dioxide-fixing enzyme which requires biotin, pyruvate: carbon dioxide ligase (6.4.1.1) has been demonstrated in autotrophic bacteria (M. I. H. Aleem, personal communication).

For such a consideration to be of general importance, autotrophic cells which contain low levels of biotin should take up appreciable quantities of this vitamin while autotrophic cells with high endogenous biotin (that is, where biotin is not a limiting factor) should not. In the latter case a second coenzyme in a sequence which includes a biotin enzyme should be the limiting factor. The first part of this hypothesis was confirmed by our finding that one autotrophic bacterium, *N. agilis*, which contains half as much endogenous biotin as does another autotrophic bacterium, *N. europaea*, took up exogenous biotin while *N. europaea* did not. We thank the U.S. National Institutes of Health for a grant.

### Timber, *Tetrameles nudiflora* R., resistant to Teredid Borers in Bombay Harbour

THE destruction by wood-borers of timbers used for marine construction has been a serious problem in both temperate and tropical waters. This communication directs attention to the resistance of the timber *Tetrameles nudiflora* to attack by marine boring organisms. This is interesting in view of the fact that this timber has been graded as coming under class III in respect of durability on land as assessed in grave-yard trials<sup>1</sup>.

Untreated panels of *T. nudiflora* (12 in. × 3 in. × 0.5 in.) were immersed in the sea at three widely separated sites in Bombay Harbour. Sixteen panels were immersed at each site together with an equal number of *Abies pindrow* (Himalayan fir) panels which served as controls. Damaged controls were replaced normally after every 3 months.

The exposures were carried out from July 1962 to September 1965. There were four separate exposures (Table 1).

Table 1

Exposure I:	from 9-7-62 to 21-8-63:	14 months
Exposure II:	from 9-7-62 to 20-3-64:	20 months
Exposure III:	from 20-3-64 to 17-10-64:	7 months
Exposure IV:	from 20-3-64 to 1-9-65:	18 months

The samples exposed to attack were examined at intervals of 3 months by sectioning to determine the extent of internal deterioration. The control panels were examined in a similar manner.

The teredid borers reported<sup>2</sup> from Bombay waters are *Bankia* (*Bankiella*) *carinata* G., *B. (Liliobankia)-companellata* M.R., *Teredo (Kuphus) manni* W., *T. (Bactronophorus) thoracites* G., and *T. (Teredo) elongata* Q. The

presence of *T. furcifera*, a synonym of *T. parksi*, and also *Lyrodus pedicellatus* has recently been observed by us. The incidence of the last two *Teredo* borers and *B. companellata* at the sites of exposure for the past 4 years has been very heavy.

Periodical examination of the test panels revealed that none of these was damaged by the teredid worms, *Teredo* and *Bankia*, at any time during their exposure. At one of the sites (Trombay) some panels did show attack of *Martesia* sp., but this was not surprising as this pholad is well known for its catholic preference. The control timber panels were heavily attacked and damaged by all types of borers within about 3 months of exposure.

Microscopic examination of the exposed test panels revealed the presence of innumerable entry holes or larval pits of 0.25 mm diameter, with the dead remains (chitinous shells) of the veliger larvae. It was therefore evident that although there had been initial anchorage or attack, there had been no progress in burrowing and the larvae had died. On almost all occasions, the larvae suffered death before their chitinous shells were transformed into calcareous ones. The superficial attack of the larvae did not impair the strength of the timber panels tested.

With a view to confirming the field exposure results described previously, the laboratory exposures of this timber were also made. The larvae of *T. furcifera* were used as the test organisms, as recommended by Becker<sup>2</sup>. This borer<sup>3</sup> has been found to be a very convenient test organism for the experimental work. Small pieces of *T. nudiflora* were offered for the attack of the teredid larvae. The timber pieces of *Abies pindrow* (Himalayan fir) were used as controls. Figs. 1a and b illustrate the damage suffered by *T. nudiflora* and *A. pindrow*. The results obtained in the laboratory tanks were similar to those obtained on the raft trials in the open sea.

I thank Shri S. K. Ranganathan and Shri C. P. De for their advice and encouragement.

### New Type of Nuclear Life Cycle in *Hemileia vastatrix*

*Hemileia vastatrix*<sup>1</sup> is the cause of rust disease of coffee, and there have been many investigations of its life cycle. This rust is characterized by the formation of non-resting teliospores which germinate *in situ* and produce sporidia, which, however, are unable to reinfect coffee, which suggests that they are non-functional<sup>2-4</sup>. Pycnial and aecial stages of this rust are not known. We have conducted further investigations of the life cycle of and mode of perennation of this fungus, with special emphasis on nuclear behaviour.

Fresh leaf material in various stages of infection was fixed in Carnoy's fluid for 1 h, then kept in 'Craf' A and B for 24 h, washed, dehydrated and embedded in paraffin wax according to the usual procedure. Sections 10μ thick were cut. Nuclei were stained with iron haematoxylin, crystal violet, and Feulgen. Temporary mounts were made in acetocarmine.

The results obtained show that the parasitic hyphae are dikaryotic (A and B in Fig. 1) in the initial stages, and later become diploid and monokaryotic through fusion of the dikaryons (Q). This nuclear status is maintained in the stromatal hyphae, the sporogenous hyphae as well as the spore mother cells (D and F). The single diploid nucleus in the spore initials divides mitotically

Fig. 1. Teredo attack under laboratory conditions. a, Surface view of the test piece of *Tetrameles nudiflora*; b, cross-section of the control *Abies pindrow*. (×3.)

(F), and one of the two daughter nuclei moves towards the base which ultimately becomes the stalk cell (G and H).

The diploid nucleus in the spore mother cell enlarges and undergoes a division, which shows all the typical features of meiosis, involving formation of bivalent pairs with chiasmata (J and K) and resulting in typical meiotic diads (L). The stage of meiotic diads is prolonged by the suspension of meiosis. Consequently, this meiotic diad has been mistaken previously for a dikaryophase associated with the formation of normal urediospores, but which actually represents a transient non-septate haplophase in the course of abnormally suspended or arrested meiosis.

Usually, nuclear fusion among rust fungi is followed immediately by initial or zygotic meiosis and is associated with teliospores. The abnormal phenomena described above thus represent unusual prolongation of the fused diplophase of the life cycle and an abnormally suspended meiosis following its first reduction division. The abnormal meiotic diad is prolonged and just precedes the infective phase after the completion of the second meiotic division. The nuclear constitution of this meiotic diad is not comparable with that of normal urediospores. This prolonged meiotic diad may therefore be designated as uredinoid teliospore for convenience.

On germination this uredinoid teliospore puts out a "pseudo-promycelium" which terminates in a structure like an appressorium (M), where the meiotic diad undergoes a second division of meiosis to produce a meiotic tetrad (N). The appressorium containing the meiotic tetrad puts out a bifid infection "peg", each arm of which receives a pair of haploid nuclei from the meiotic tetrad (O). If two nuclei out of four are sorted at random in each of the two infection "pegs", there could be some scope for genetic variation depending on the degree of genetic heterozygosity in the original somatic hyphal nuclei. Compared with the normal process of hybridization in other rusts, scope for genetic variations in such life cycles would be relatively restricted. This probably explains the abnormally low number of biotypes reported in this rust

fungus. In the last stage of the life cycle bifid infection "pegs" reinfect the host and repeat the life cycle (A).

I propose to name this new type of life cycle of rust fungi "Kamat type" after Prof. M. N. Kamat, head of the Mycology Division, M.A.C.S. Poona, India. I thank Dr. G. B. Deodikar, director of M.A.C.S., Poona, India, for his help.

### Influence of Vesicular-arbuscular Mycorrhizas on the Uptake of Phosphorus-32 by *Liriodendron tulipifera* and *Liquidambar styraciflua*

ECTOTROPHIC mycorrhizas are capable of enhancing the uptake of nutrients by the host plant, and they have been shown to absorb and accumulate more ions than non-mycorrhizal roots<sup>1-3</sup>. It has also been shown that the fungus sheath can absorb ions and release a fraction of them to the host plant<sup>1</sup>. There is much less evidence, however, that nutrient uptake and ion accumulation are enhanced by the endotrophic vesicular-arbuscular mycorrhizas where there is no fungus sheath but only an extensive external and internal hyphal development<sup>4</sup>. Plants with vesicular-arbuscular mycorrhizas contain more nutrients than the non-mycorrhizal control plants<sup>5-7</sup>. Soil in which mycorrhizal plants have grown contains less phosphorus than soil in which non-mycorrhizal control plants have grown<sup>8,9</sup>. This evidence indicates that vesicular-arbuscular mycorrhizas may function in a manner similar to the ectotrophic type by increasing the absorption of ions by the host plants.

The purpose of our investigation was to determine whether vesicular-arbuscular mycorrhizas of sweetgum (*Liquidambar styraciflua* L.) and tuliptree (*Liriodendron tulipifera* L.) enhance phosphorus-32 uptake. The fungus used in our experiments, *Endogone fasciculata* Thaxter, has not been obtained in pure culture on artificial media and it was maintained on the roots of living maize grown in sterilized soil<sup>8</sup>. Sweetgum and tuliptree seedlings were inoculated by growing them in steam sterilized soil to which chopped maize roots containing *E. fasciculata* had been added. The control plants were grown in sterilized soil to which an equal quantity of autoclaved chopped mycorrhizal roots had been added. In order to introduce the contaminating bacteria and fungi present on the mycorrhizas into the control pots, the infected roots were washed in distilled water and the wash water was filtered through a sieve with openings 44 $\mu$  wide. Some of this filtrate (30 ml.) was added to the soil in each of the control pots.

In the first experiment, individual 90 day old mycorrhizal and non-mycorrhizal tuliptree seedlings were transferred to separate containers with an aerated solution of 1.083  $\times 10^{-4}$  molar phosphate. A carrier-free solution of phosphorus-32 containing 8.7  $\mu$ c. was then added to each container. After 4 days the plants were removed from the solution of phosphorus-32. The roots were then rinsed in a solution of 0.001 molar phosphate, rinsed twice in distilled water, blotted, and dried for 24 h at 45° C. Root samples were collected at random from each plant and wet washed in a mixture of nitric and sulphuric acid and neutralized with sodium hydroxide. The radioactivity in each sample was determined by placing a 0.1 ml. aliquot on a planchet and counting the samples under a gasflow detector connected to a scaler. Each sample was counted

Fig. 1.

under the same conditions of sample geometry and counter efficiency. The radioactivity in the roots of the mycorrhizal tuliptree seedlings was greater than that in the non-mycorrhizal seedlings (Table 1). The experiment was repeated and similar results were obtained.

Table 1. RADIOACTIVITY OF THE ROOTS OF 90 DAY OLD MYCORRHIZAL AND NON-MYCORRHIZAL TULIPTREE SEEDLINGS AFTER 4 DAYS IN A SOLUTION OF PHOSPHORUS-32

	Mean activity (c.p.m./mg dry weight)*
Mycorrhizal tuliptree seedlings	6,416†
Non-mycorrhizal tuliptree seedlings	3,365

\* Means based on five replications.

† Difference between means significant at the 5 per cent level.

In another experiment, 95 day old mycorrhizal and non-mycorrhizal sweetgum seedlings were transferred to individual pots containing steam-sterilized soil, and allowed to grow for 40 days. A solution of phosphorus-32 containing 14  $\mu$ c. was injected into the soil of each pot in six places around each plant and the plants were grown for six days. To ensure uniform counting geometry for assay of radioactivity, duplicate circular leaf pieces, 5 mm in diameter, were taken from the first leaf below the developing terminal leaf of each plant. The radioactivity of these intact leaf pieces was then determined with a gas flow detector connected to a scaler. The foliage of the mycorrhizal plants showed much higher radioactivity than did the foliage of the controls (Table 2).

Table 2. RADIOACTIVITY OF THE FOLIAGE OF MYCORRHIZAL AND NON-MYCORRHIZAL SWEETGUM SEEDLINGS GROWN IN A STERILIZED SOIL CONTAINING PHOSPHORUS-32

	Mean activity in foliage (c.p.m./mg fresh weight)*
Mycorrhizal sweetgum seedlings	353†
Non-mycorrhizal sweetgum seedlings	24

Seedlings were 135 days old.

\* Means from 6 replications with 2 subsamples and 4 replications with 2 subsamples.

† Difference between means significant at 1 per cent level.

The results from these experiments indicate that vesicular-arbuscular mycorrhizas enhance the uptake of phosphorus-32 by the host plant from nutrient solution and from soil, and indicate that the function of vesicular-arbuscular mycorrhizas is similar to that of ectotrophic mycorrhizas.

## MICROBIOLOGY

### Routine Method for Concentration and Partial Purification of a Murine Leukaemia Virus (Rauscher)

MURINE leukaemia viruses are generally obtained either from plasma or tissues of leukaemic mice or from tissue culture supernatants by differential centrifugation in a citrate buffer, as described by Moloney<sup>1</sup>. This method, however, results in loss of about 90 per cent of the initial leukaemic activity<sup>2</sup>.

We describe here a simple modification of the Moloney procedure, suggested by the work of Mrs. N. Plus on the sigma virus of *Drosophila*<sup>3</sup>, which enables concentration and partial purification of the Rauscher virus without any loss in leukaemic activity.

The source of Rauscher virus is plasma from *BALB/c* mice, 1 month old, inoculated intraperitoneally with 0.1 ml. of a suspension containing  $10^5$ – $10^6$  *E.D.*<sub>50</sub>/ml. of virus. The mice are killed 28 days later and their blood is collected and pooled; it is then prepared by one of two methods.

In Moloney's method blood is collected and supplemented with an equal volume of 0.306 molar potassium citrate buffer, pH 6.8. This is made clearer by low speed centrifugation in a refrigerated centrifuge; first at 1,200g for 20 min and then at 2,400g for 20 min. All later steps are carried out in the cold at 4° C. The upper and lower parts of the supernatant in the centrifuge tube are discarded; the middle part which represents two thirds of the supernatant is collected and the virus suspension is centrifuged for 2 min at 10,000g. The supernatant is finally centrifuged at 56,000g for 90 min. Following this procedure the virus pellet is resuspended with a 'Teflon' pestle homogenizer in a volume of 0.05 molar sodium citrate buffer, pH 6.8, equal to the original volume of the virus suspension just before ultracentrifugation.

In our proposed modifications leukaemic blood is collected in the same manner and mixed with a concentrated heparin solution in distilled water. The final heparin concentration is 10–15  $\mu$ g/ml. of blood. The same procedure as in Moloney's method is used for the low speed centrifugations. The supernatant of a third centrifugation at 10,000g for 2 min is mixed volume for volume with a solution containing 0.5 molar sucrose and 0.00075 molar *tris*-buffer, pH 7.2, and then ultracentrifuged for 90 min at 56,000g. The virus pellet is resuspended using a 'Teflon' pestle homogenizer, in a solution containing 0.25 molar sucrose and 0.00075 molar *tris*-hydrochloric acid, pH 7.2.

Bioassays for leukaemogenic activity are carried out by inoculation of tenfold dilutions of each sample into female *BALB/c* mice aged 5–6 weeks. Ten mice are inoculated intraperitoneally with 0.1 ml. of each dilution. Mice are killed 28 days later and the animals are considered positive if the wet spleen weight exceeds 150 mg. The titre unit expressed as *E.D.*<sub>50</sub> is the dose with which 50 per cent of the animals are positive and is calculated according to the cumulative method of Reed-Muench (standard deviation is  $\pm 0.30$  log). The results are quite reproducible and have been examined elsewhere (report by Levy, in preparation).

Table 1. LEUKAEMOGENIC ACTIVITY OF RAUSCHER VIRUS EXTRACTED FROM *BALB/c* MOUSE PLASMA

Experiment	Method	Leukaemogenic activity before ultracentrifugation ( <i>E.D.</i> <sub>50</sub> /ml.)	Leukaemogenic activity after ultracentrifugation ( <i>E.D.</i> <sub>50</sub> /ml.)*	Percentage of infectivity recovered (Per cent) (Average)
(1)	Citrate	$10^{4.56}$	$10^{3.55}$	6
(2)		$10^{4.10}$	$10^3$	5
(3)		$10^{4.08}$	$10^{3.50}$	18.5
(4)		$10^{4.08}$	$10^{3.87}$	15
(5)		$10^{4.10}$	$10^{4.10}$	9
(6)	Sucrose	$10^{4.08}$	$10^{3.87}$	0.5
(7)		$10^{4.50}$	$10^{4.45}$	71
(8)		$10^{4.56}$	$10^{4.78}$	130
(9)		$10^4$	$10^4$	100

\* In each instance, virus pellets were resuspended in a volume of buffer equal to the original volume of the virus suspension just before ultracentrifugation.

Comparative results of both purification procedures are given in Table 1. It can be seen that about 90 per cent of leukaemogenic activity is lost when the citrate method is used, while the sucrose method gives a complete recovery of the initial leukaemogenic activity. These data clearly demonstrate the usefulness of sucrose medium for the concentration and partial purification of Rauscher virus and possibly other murine leukaemogenic viruses.

Further purification can be achieved in sucrose gradients as we have shown by the more detailed work reported elsewhere (report in preparation).

These observations suggest that ultracentrifugation is not in itself responsible for inactivation. We have observed

already that very fast or long run centrifugation does not cause any further inhibition of the leukaemogenic activity of Rauscher virus. Furthermore, citrate medium is not directly responsible for the loss of activity, because virus kept in this medium for prolonged periods is preserved entirely<sup>2</sup>. These facts suggest that osmotic pressure or ionic effects alone are not directly responsible for virus inactivation which seems to be caused by the concentration in a salt solution. On the other hand, centrifugation in non-ionic gradients, such as polyglucose and polysucrose<sup>4</sup> or sucrose<sup>5</sup>, preserves the biological activity of Rauscher virus.

In addition it may be pointed out that after one log loss of activity after the preparation of pellets in citrate buffer, partial recovery (0.5–0.7 log) occurs when the virus is centrifuged in a sucrose gradient. This suggests that the virus concentration in ionic media strongly affects its leukaemogenic activity. This inhibition may be caused by an aggregation of particles.

## CYTOLOGY

### Inhibition of Migration of Rat Peritoneal Exudate Cells by Ascites Tumour Fluid Fractions

FACTORS in the ascitic fluid of rats bearing a Walker 256 carcinosarcoma are capable of inhibiting the amoeboid motility of peritoneal exudate cells. This finding may be pertinent to evidence that a tumour interferes with the host's immunological mechanisms<sup>1</sup>.

The tumour was carried in male Wistar rats. Normal rats of the same strain were given an intraperitoneal injection of 2 ml. of a 10 per cent solution of sodium caseinate in 0.14 molar saline. Twenty-four hours after injection, the peritoneal cavity was washed with Hartman's solution. The cell population obtained consisted of approximately 80 per cent mononuclear cells and 20 per cent polymorphonuclear leucocytes. These cells were then made up to be 10 per cent by packed volume in minimum essential Eagle's medium fortified with 15 per cent normal rat serum and containing 100 u of penicillin G/ml. and 100 µg of streptomycin sulphate/ml. Small capillary tubes (non-heparinized, 1.3 to 1.5 mm in diameter, 75 mm long) were filled with the cell suspension, sealed at one end, and centrifuged. The capillary tubes were cut at the cell-fluid interface and the portions containing the cells were placed in Petri dishes and secured with a small drop of paraffin. Six millilitres of the medium used for suspension, or a combination of the medium and ascitic fluid in a total volume of 6 ml., were added to the Petri dishes, which were then placed in an incubator at 37° C and left for 24 h. The extent of migration of the peritoneal exudate cells was then measured by centrifuging from the culture medium the cells which had migrated out of the capillary tubes, resuspending in 0.2 ml. of Eagle's medium, and counting in a haemocytometer. The percentage inhibition of migration was expressed by

$$\frac{C - A}{C} \times 100$$

where *A* and *C* are the total number of cells migrating from the capillary tubes in cultures with and without the fraction to be tested, respectively (Fig. 1). *C* was  $1.4 \times 10^4$ – $2.1 \times 10^4$ , which represented 12 per cent to 18 per cent of the total number of cells originally in the capillary tubes. With increasing concentrations of ascitic fluid in the cultures, the inhibition of migration of the cells increases (Fig. 2). One hundred units of inhibitory activity were arbitrarily designated to be that amount of inhibition caused by 1 ml. of the tumour fluid.

Extracts of liver and kidney from normal animals were prepared by homogenization of the tissues of 3 volumes of Eagle's medium fortified with 15 per cent rat serum. The effect of the supernatant fractions of these extracts, obtained at 105,000g, on cell migration was then determined (Table 1). Increased concentrations of normal rat serum and serum from tumour bearing rats were also assayed (Table 1). These results indicate that the inhibitory effect is not an overall property of normal tissues.

Fig. 1. Migration of peritoneal exudate cells in 24 h in typical culture containing minimum essential Eagle's medium with 15 per cent normal rat serum (left) and additionally 50 per cent Walker 256 ascites tumour fluid (right).

Fig. 2. Relationship of concentration of Walker 256 ascites tumour fluid in the cell culture to inhibition of migration of peritoneal exudate cells after 24 h of incubation. Values for 1.7, 6.7, and 25.0 per cent ascitic fluid represent the average of four determinations each. Values for 33.3, 41.7, 50.0 per cent represent the average of eight, eight, seventeen, six, six, and twenty-two determinations, respectively. Remaining values represent the average of two determinations. The curve was constructed from values obtained using ascitic fluid from thirteen groups of tumour bearing rats, each group containing six to twelve animals.

Table 1. EFFECT OF TISSUE EXTRACTS AND SERUM ON MIGRATION OF PERITONEAL EXUDATE CELLS

Fraction	Concentration in culture medium (per cent)	Inhibition* (per cent $\pm$ S.D.)
Liver	8.3	-51 $\pm$ 30
Liver	16.7	-79 $\pm$ 18
Kidney	8.3	-5 $\pm$ 5
Kidney	16.7	-26 $\pm$ 50
Normal serum†	50.0	-3 $\pm$ 16
Walker 256 serum	50.0	-3 $\pm$ 8

\* Values for percentage inhibition represent mean values  $\pm$  S.D., each based on four determinations. Negative values indicate that migration was stimulated rather than inhibited.

† Serum from non-tumour-bearing rats.

Table 2. EFFECT OF EIGHT TREATMENTS OF WALKER 256 ASCITES TUMOUR FLUID ON ITS ABILITY TO INHIBIT *in vitro* MIGRATION OF PERITONEAL EXUDATE CELLS

Treatment	Concentration in culture medium (per cent)	Inhibition (per cent)
Normal collection (22° C, 30 min)	50.0	92 $\pm$ 5
4° C, 13 days	50.0	58 $\pm$ 5
22° C, 8 h	50.0	55 $\pm$ 24
56° C, 30 min	50.0	-30 $\pm$ 24
Dialysis, 24 h, 4° C	50.0	91 $\pm$ 8
Lyophilization	50.0	54 $\pm$ 11
Normal collection (22° C, 30 min)	16.7	53 $\pm$ 13
-4° C, 1 month	16.7	59 $\pm$ 9
4° C, 24 h	16.7	49 $\pm$ 9
'Pronase', 2 PUK/mg of protein*, 24 h, 4° C	16.7	7 $\pm$ 18

Values for percentage inhibition represent mean values  $\pm$  S.D. Each value is the average of four determinations except normal collection (16.7 and 50.0 per cent concentration), dialysis, and 'Pronase'. These values represent 9, 21, 7, and 8 determinations, respectively. Dialysis was performed against three changes of glass double distilled water, pH 6.7.

\* 'Pronase' units are expressed according to Nomoto *et al.*<sup>2</sup>.

The results of preliminary studies aimed at the elucidation of the nature of the inhibitory activity are summarized in Table 2. These data suggest that the activity is associated with a labile macromolecule which is either a protein or is associated with a protein. It was necessary to carry out the 'Pronase'<sup>2</sup> incubation at 3° C, and so the action of this protease derived from *Streptomyces griseus* was possibly incomplete. That 'Pronase' alone had no effect on migration was shown by adding an equal amount of 'Pronase' to cultures containing only the culture medium.

We determined whether the inhibitory effect occurred in an ascitic fluid produced by an agent other than a tumour. Non-tumour ascitic fluid was produced with complete Freund's adjuvant according to the method of Munoz<sup>3</sup>. The non-tumour ascitic fluid which was allowed to clot exhibited no inhibition, whereas that which contained 1.2 mg of disodium ethylenediamine tetraacetate (sodium EDTA)/ml. as anticoagulant showed a moderate level of activity (Table 3). This observation indicated that either fibrinogen or a protein involved in the clotting mechanism may be responsible for the inhibitory effect. When plasma from healthy rats was assayed, it was also found to be inhibitory (Table 3).

The tumour ascitic fluid seldom clotted and the level of inhibitory activity was twice as high as that of the non-tumour ascitic fluid, and so it appeared that an inhibitory protein may be present in the tumour fluid which is not present in other fluids.

The Walker 256 ascites tumour fluid (sufficient to contain an average of 45 mg of protein) was subjected to preparative electrophoresis in 5 per cent acrylamide gel<sup>4</sup>, using *tris*-EDTA-boric acid buffer, pH 8.32 (ref. 5), at

Table 3. EFFECT OF ASCITIC FLUID AND PLASMA FROM NON-TUMOUR-BEARING ANIMALS ON PERITONEAL EXUDATE CELL MIGRATION

Sample	Treatment of sample	Concentration in culture medium (per cent)	Inhibitory activity* (U)
TAF†	None	16.7	100
N-TAF‡	Clotted	16.7	0
N-TAF	Sodium EDTA	16.7	50
Normal rat plasma	Sodium EDTA	16.7	103
	Sodium EDTA	—	20

\* Each value represents the average of eight determinations.

† Walker 256 ascites tumour fluid.

‡ Non-tumour ascitic fluid induced with complete Freund's adjuvant.

Fig. 3. Protein bands from Walker 256 ascites tumour fluid on acrylamide gel. The anode compartment was at the right as positioned here. Amido-Schwartz stain in acetic acid. (a) Photograph of preparative gel; (b) schematic diagram of the preparative gel,  $\times 0.9$  the scale (a), showing the approximate centres of regions later isolated.

300 V, which resulted in a current of approximately 150 mAmp when terminated after 3.5 h (Fig. 3). The protein fractions were subsequently recovered by elution convection electrophoresis<sup>6</sup> (Table 4). The total protein recovery averaged 50 per cent. The designations of these directly derived fractions were identical with the arbitrary regional labels given to the stained bands on the preparative gel (Fig. 3). Two of the elution convection electrophoresis fractions (designated B and prealbumin) were found to be inhibitory (Table 4, Fig. 3 at arrows); the other fractions stimulated migration. In the six experiments of Table 4, fraction B was found to be inhibitory in four experiments only, while the prealbumin fraction was inhibitory in all six.

Table 4. ASSAY OF PROTEIN FRACTIONS OF WALKER 256 ASCITES TUMOUR FLUID OBTAINED FROM ACRYLAMIDE GELS BY ELUTION CONVECTION ELECTROPHORESIS\*

Fraction	Inhibition (per cent)	Inhibitor activity (U)	Total protein in culture (mg)	Inhibitor specific activity (U/mg protein)
TAF†	46	100	21	4.8
Origin‡	-18	0	0.26	0
A†	-15	0	0.25	0
B†	8	15	0.22	36.4
C†	-26	0	0.52	0
D†	-38	0	0.95	0
Albumin‡	-40	0	1.89	0
Prealbumin‡	20	40	0.16	250.0

Negative values represent a stimulation of migration.

\* Values for Walker 256, fraction B, and prealbumin fraction represent the average of six experiments with four replicates in each experiment. Other values represent two experiments with four replicates.

† Unfractionated Walker 256 ascites tumour fluid.

‡ Fraction obtained from region so designated in Fig. 3.

Using analytical acrylamide gel electrophoresis the B fractions of tumour ascitic fluid and the fractions from the region comparable with B for sodium EDTA-treated non-tumour ascitic fluid, and for plasma, were each resolved into three components, whereas only two components were observed in the fractions from the comparable region to B derived from serum and from clotted non-tumour ascitic fluid. On the basis of these electrophoretic results, fraction B is thought to contain the protein responsible for the inhibitory activity previously mentioned found in plasma and in sodium EDTA-treated non-tumour ascitic fluid, that is, fibrinogen.

The prealbumin fraction from the tumour fluid was subjected to further electrophoresis in glycine and sodium hydroxide buffer, pH 9.6 (Fig. 4), and in sodium succinate

## AGRICULTURE

## Influence of Diet on the Behaviour Pattern of Sheep

BALCH<sup>1</sup> noted that under normal management adult sheep and cattle sleep little if at all. He suggested that this behaviour pattern may be related to the need for maintaining the thorax in an upright position for proper functioning of the reticulo-rumen, and to the requirement of time and consciousness for rumination. He defined sleep as a marked relaxation of consciousness and especially of vision and hearing ability. The following observations on the behaviour of ewes would seem to support the suggestion that the typical sleepless behaviour pattern is connected with the requirements for rumination.

Six ewes were kept in 3 m × 3 m pens, where they had free access to water and to pellets of finely ground dried grass. They also received daily 2 kg of a conventional concentrated mixture for ewes which was given in two meals at the two daily milking times. While the ewes were on this diet no rumination was observed. This is in accordance with earlier reports of an absence of rumination when animals are fed on diets in which all the roughage is finely ground<sup>2</sup>. The pens were brightly illuminated throughout the period. After an initial period of 14 days, during which the animals remained healthy and milked normally, experimental treatments were applied. These consisted of an hourly injection of 9 units of oxytocin through a semi-permanent jugular cannula. Every hour the ewes were taken from their pens and walked 20 m through a passage into the milking parlour, injected and then returned to their pens. After the first few hours of treatment the ewes began to show obvious signs of fatigue and even of exhaustion. Their walk became slow and they had to be pushed through to the parlour. Three of the ewes had periods of panting. Most striking was their behaviour between injections. They lay down in a quite atypical position with the head straight out between the forelegs and the thorax fully inclined. The position was similar to that of a sleeping pig or dog. Their eyes were closed and the ewes did not respond to any noise or the approach of the experimenter. It was necessary to prod them repeatedly in order to awaken them from what, in the terms of the definition above, was a deep sleep. The milk yield dropped 15 per cent over the 4 days of the treatment.

On the advice of Dr. C. C. Balch, roughage was added to the diet; the ewes were offered hay *ad lib.* for 1.5 h every evening. This resulted in a dramatic recovery; rumination was observed within 2 h of the first hay meal and within 4 h all the obvious signs of distress and exhaustion had disappeared. No panting was observed. Between injections the ewes lay down in a typical position, with the thorax held upright and eyes open; their hearing was alert, and on many occasions rumination was observed. When the experimenter approached the pens for the hourly injection the ewes stood up and moved towards the gate of the pen in anticipation. The milk yield increased at the morning milking following the first meal of hay and had regained the earlier level by the next evening. Although the injections were continued in this group of ewes for a further 5 days, and subsequently on other groups of ewes for similar periods, no recurrence of the unusual behaviour was observed.

These observations suggest that ewes which were not ruminating, because of the finely ground diet, needed to sleep for considerable periods and were greatly upset when disturbed hourly. This need for sleep disappeared when the ewes were given hay and they began to ruminate.

Fig. 4. Vertical acrylamide gel electrophoresis of prealbumin fraction of Walker 256 ascites tumour fluid in glycine buffer, pH 9.6. Origin was at top and anode compartment was proximal to base. Prealbumin applied was initially isolated from the tumour fluid by elution convection electrophoresis from acrylamide gels after electrophoresis in *tris*-EDTA-boric acid buffer, pH 8.3.

buffer, pH 5.2. In both buffers, this fraction migrated as a single band. This fraction was found to exhibit inhibitory activity at a concentration as low as 6 µg of protein/ml.

The hexose and hexosamine bound to protein were determined for the electrophoretically isolated prealbumin fraction from the tumour fluid according to the techniques of Winzler<sup>7</sup>. On the basis of Lowry protein determinations the prealbumin was calculated to contain 2.6 per cent hexose and 0.9 per cent hexosamine.

Work possibly relevant to the foregoing data includes reports of fibrin as a cancer-distinctive substance<sup>8</sup>; the finding that the intravenous injection of a polysaccharide fraction extracted from Ehrlich ascites tumour cells into rabbits results in impaired migration of peripheral blood leucocytes *in vitro*<sup>9</sup>; and a report that a mucoprotein fraction derived from human plasma and urine is inhibitory to cell migration<sup>10</sup>.

Statistical advice and critical comment were given by Dr. Roger Flora and Dr. Alfred J. Crowle respectively. This work was supported by a U.S. Public Health Service Cancer Training Grant.

## FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

## Monday, January 9

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion meeting on "Recent Developments in Fuel Cells" opened by Dr. D. P. Gregory.

INSTITUTION OF ELECTRICAL ENGINEERS (joint discussion meeting with the Automatic Control Group of the Institution of Mechanical Engineers, at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Meeting on "The Application of Data Processing in a Large Manufacturing Plant".

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 6 p.m.—"The Great Highway" (colour films).

## Tuesday, January 10

PHYTOCHEMICAL GROUP (at the School of Pharmacy, Brunswick Square, London, W.C.1)—Symposium on "Plant Tissue Culture".

ROYAL SOCIETY OF MEDICINE, EXPERIMENTAL MEDICINE AND THERAPEUTICS SECTION (at 1 Wimpole Street, London, W.1), at 2 p.m.—Symposium on "Protein Metabolism".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. F. A. Benson and other speakers: "Glow and Corona Discharge Tubes".

INSTITUTION OF THE RUBBER INDUSTRY (at the Eccleston Hotel, Victoria, London, S.W.1), at 5.30 p.m.—Mr. J. Batchelor: "Practical Aspects of Rheology in Polymer Processes"; 7 p.m.—"New Polymers".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 5.30 p.m.—Sir Harrie Mussey, F.R.S.: "Problems of Science Policy" (Civil Service Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 6 p.m.—Discussion meeting on "Are the Safety Arrangements on British Aircraft Electrical Systems Entirely Logical?" opened by Mr. D. O. Burns.

SOCIETY OF CHEMICAL INDUSTRY, OILS AND FATS GROUP (at 14 Belgrave Square, London, S.W.1), at 6.15 p.m.—Prof. G. B. Martinenghi (University of Milan): "New Process for the Simultaneous Refining and Deodorization of Fats and Oils".

PLASTICS INSTITUTE, LONDON SECTION (at Imperial Chemical House, Millbank, London, S.W.1), at 6.30 p.m.—Mr. W. R. Groves: "Injection Moulding of Thermosets".

## Wednesday, January 11

INSTITUTE OF METALS (at 17 Belgrave Square, London, S.W.1), at 11 a.m.—Discussion: "The Newer Metals" (Meeting for Young Metallurgists).

SOCIETY OF CHEMICAL INDUSTRY, MICROBIOLOGY GROUP (joint meeting with the Society of Applied Bacteriology, at the Royal Society of Medicine, 1 Wimpole Street, London, W.1), at 2.15 p.m.—Meeting on "Aspects of Air Sterilization".

GEOLOGICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. G. Whittle: "Photogeology in Overseas Geological Aid: Aspects of the Work of the Photogeological Division of the Institute of Geological Sciences" (Demonstration); Dr. J. V. Hepworth: "Photogeological Recognition of Ancient Organic Belts in Africa" (Paper).

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion meeting on "High-speed Fuses for the Protection of Diodes and Thyristors" opened by Mr. E. Jacks.

SOCIETY OF INSTRUMENT TECHNOLOGY (at Manson House, 26 Portland Place, London, W.1), at 5.30 p.m.—Mr. A. H. Weaving, Mr. T. A. Wesolowski-Low and Mr. J. A. Izacott: "Quantitative Safety".

SOCIETY OF ENVIRONMENTAL ENGINEERS (in the Mechanical Engineering Department, Imperial College, London, S.W.7), at 6 p.m.—Dr. B. L. Clarkson: "Acquisition and Analysis of Random Data".

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN (at 17 Bloomsbury Square, London, W.C.1), at 8 p.m.—Mr. G. Smith: "Eye Drops".

## Thursday, January 12

INSTITUTE OF PETROLEUM, ECONOMICS AND OPERATIONS GROUP (at 61 New Cavendish Street, London, W.1), at 5.30 p.m.—Mr. C. C. D. Miller: "Labour Aspects of Joining the Common Market".

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, London, S.W.1), at 5.30 p.m.—Informal Discussion on "Expediting the Road Programme" introduced by Col. S. Maynard Lovell.

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion meeting on "M.H.D. Generation" opened by Dr. P. R. Howard.

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 5.30 p.m.—Lord Bowden: "Problems of Research in Universities and Government Establishments" (Civil Service Lecture).

## Friday, January 13

INSTITUTION OF ELECTRICAL ENGINEERS (joint meeting with the I.E.R.E. Medical and Biological Group, at Savoy Place, London, W.C.2), at 10.30 a.m.—Colloquium on "Standardization, Servicing, Maintenance and Organization of Medical and Biological Instrumentation".

ASSOCIATION OF APPLIED BIOLOGISTS (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 10.60 a.m.—General Meeting followed by a Symposium on "The Biology of *Heterodera*".

## Monday, January 16

SOCIETY OF CHEMICAL INDUSTRY, PESTICIDES GROUP (at 14 Belgrave Square, London, S.W.1), at 5 p.m.—Dr. J. E. Norris: "The Use of Insect Pathogens for the Control of Pest Species".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion meeting on "Laboratory Work Policy" opened by Dr. K. R. Sturley and Mr. A. D. Collop.

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—The Right Hon. Viscount Watkinson, P.C., C.H.: "Industry" (first of four Cantor Lectures on "Some Aspects of the U.S.A. Today").

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Prof. R. Y. Jennings and Dr. P. E. Kent: "Sea Bed Discoveries and International Law".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURERS (2) IN THE DEPARTMENT OF ELECTRONICS in the fields of integrated circuit design, or digital systems, or computer element design—The Deputy Secretary, The University, Southampton (January 12).

LECTURERS OR ASSISTANT LECTURERS IN THE DEPARTMENT OF MATHEMATICS in one or more of the following subjects: (a) numerical analysis; (b) theoretical physics, in particular the theory of electrons or light scattering; (c) statistics; (d) theoretical mechanics—The Registrar, The University of Manchester Institute of Science and Technology, Sackville Street, Manchester, 1 (January 13).

ASSISTANT LECTURERS OR LECTURERS (2) (graduates with research experience either in inorganic chemistry or in the physical properties of polymers) IN THE DEPARTMENT OF CHEMISTRY—The Registrar, University of Essex, Wivenhoe Park, Colchester, Essex (January 16).

LECTURER IN STATISTICS—The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1 (January 16).

LECTURER (with research experience in physical chemistry) IN CHEMISTRY—The Registrar, University College of North Wales, Bangor, North Wales (January 16).

LECTURER OR ASSISTANT LECTURER (with interests in some aspect of either systematic or regional geography) IN THE DEPARTMENT OF GEOGRAPHY—The Deputy Secretary, The University, Southampton (January 17).

BIOCHEMIST (with an honours degree in science (majoring in biochemistry) or equivalent, and suitable research experience) IN THE SOIL BIOCHEMISTRY DEPARTMENT for research on legume nitrogen fixation—The Director, An Foras Taluntais (The Agricultural Institute), 33 Merrion Road, Dublin, 4, Republic of Ireland (January 26).

LECTURER IN THE LARGE ANIMAL TEACHING UNIT based at the Veterinary Field Station, Royal (Dick) School of Veterinary Studies, Easter Bush, Roslin, Midlothian—The Secretary, University of Edinburgh, Old College, South Bridge, Edinburgh (January 27).

SENIOR DEMONSTRATOR (with a degree in science, preferably with honours, and some teaching experience, with specialization in zoology) IN ZOOLOGY at the University College of Townsville, University of Queensland, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (London and Brisbane, January 27).

LECTURER (preferably with an interest in problems of the atmosphere) IN PHYSICAL OCEANOGRAPHY—The Registrar (Room 39, O.R.B.), The University, Reading (January 28).

LECTURER (with a special interest in some branch of atmospheric physics or in dynamical meteorology) IN METEOROLOGY—The Registrar (Room 39, O.R.B.), The University, Reading (January 28).

LECTURER IN APPLIED MATHEMATICS in the School of General Studies, Australian National University—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, January 30).

BIOLOGISTS (2) to work on the behaviour and physiology of bees—The Secretary, Rothamsted Experimental Station, Harpenden, Herts, quoting Ref. No. 1052/95 (January 31).

LECTURER (with considerable field experience of geology) IN GEOLOGY AND MINERALOGY—The Secretary, The University, Aberdeen (January 31).

RESEARCH ASSISTANT (graduate (or equivalent) in physics, engineering or textile technology) IN THE DEPARTMENT OF TEXTILE TECHNOLOGY to work on the development of woven, knitted and other fabrics—The Registrar, The University of Manchester Institute of Science and Technology, Sackville Street, Manchester, 1 (January 31).

SENIOR RESEARCH FELLOW OR RESEARCH FELLOW IN CHEMISTRY—The Registrar, University of Kent at Canterbury, Canterbury, Kent, quoting Ref. A28 (January 31).

SENIOR TUTOR/DEMONSTRATOR IN GEOGRAPHY at the University of Sydney, Australia, to conduct, or to assist in, courses of human geography, with special reference to tropical areas of Africa and/or South-East Asia; and to assume some major responsibility in the operation of first-year practical classes—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, February 3).

ASSISTANT LECTURER OR LECTURER IN THE DEPARTMENT OF PHYSICS (research interests of the department include solid state and gaseous plasmas, low temperature physics, semiconductors, materials science and lasers)—The Registrar, University of Essex, Wivenhoe Park, Colchester, Essex (February 4).

SENIOR LECTURER (with a Ph.D. or comparable academic qualifications in petrology, an interest in field-work, and awareness of economic as well as the theoretical aspects of igneous petrology) IN GEOLOGY at the University of Queensland, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (London and Brisbane, February 10).

POSTDOCTORAL RESEARCH FELLOWS (2) IN THE DEPARTMENT OF PHYSICAL CHEMISTRY, to carry out a joint programme of experimental research and critical evaluation of reaction kinetic data—The Registrar and Secretary, The University, Leeds, 2 (February 14).

IMPERIAL CHEMICAL INDUSTRIES RESEARCH FELLOWS (preferably with the degree of Ph.D. or equivalent research experience, and normally below the age of 30) in various branches of Chemistry (including Inorganic Chemistry, Chemical Engineering, Engineering, Physics and allied subjects)—The Registrar, The University, Manchester, 13 (February 17).

LECTURERS AND ASSISTANTS (qualified in pure or applied mathematics) IN MATHEMATICS—Secretary of the University Court, The University, Glasgow (February 17).

RESEARCH ASSISTANT (with a Ph.D. or equivalent experience in biochemistry or organic chemistry) IN THE DEPARTMENT OF ORGANIC CHEMISTRY, to collaborate with Prof. J. Baddiley, F.R.S., in research in the field of bacterial walls, membranes and capsules—The Registrar, The University, Newcastle upon Tyne, 2 (February 28).

ASSISTANT OR ASSOCIATE PROFESSOR IN BIOPHYSICS—Dr. L. Katz, Head, Department of Physics, University of Saskatchewan, Saskatoon, Saskatchewan, Canada.

ASSISTANT or ASSOCIATE PROFESSORS (with a Ph.D. degree) IN THE DEPARTMENT OF PHYSICS—Prof. J. L. Ollmenhaga, Head, Department of Physics, University of Victoria, British Columbia, Canada.

BIOCHEMIST (Basic Grade) to assist in the development of a laboratory for the investigation and management of patients with kidney disease—Clerk of the Governors, St. Bartholomew's Hospital, London, E.C.1., quoting Ref. No. ASC/759.

CHIEF TECHNICIAN IN THE BIOCHEMISTRY DEPARTMENT to supervise technicians and various activities of the department, and to help in planning for the move to Guildford in 1969—The Staff Officer, University of Surrey, Battersea Park Road, London, S.W.11.

DEMONSTRATORS and RESEARCH ASSISTANTS IN THE DEPARTMENT OF CHEMISTRY—Dr. W. C. Howell, Department of Chemistry, University of Western Ontario, London, Ontario, Canada.

GRADUATE RESEARCH ASSISTANTS IN MATERIALS SCIENCE—Chairman, Department of Materials Science, Thornton Hall, University of Virginia, Charlottesville, Va., 22903, U.S.A.

JUNIOR RESEARCH FELLOW IN PHYSICS—The Secretary, Balliol College, Oxford.

JUNIOR TECHNICIAN or TECHNICIAN (preferably with "A" level chemistry) for biochemical work in a new Experimental Pathology Department—The Secretary, University College Hospital Medical School, University Street, London, W.C.1.

ORGANIC CHEMISTS (with a good honours B.Sc., or equivalent, and preferably experience in aliphatic or heterocyclic chemistry) to join a progressive research team—The Director, Arthur D. Little Research Institute, Inveresk, Musselburgh, Midlothian, Scotland.

POSTDOCTORAL RESEARCH FELLOW IN ORGANIC CHEMISTRY in the School of Chemistry, for work concerned with fungal metabolism, the structure of mold metabolites, and the biosynthesis of the gibberellins—The Registrar, The University, Leeds, 2.

PROFESSOR OF EXPERIMENTAL NUCLEAR PHYSICS—Dr. L. Katz, Director, Accelerator Laboratory, University of Saskatchewan, Saskatoon, Saskatchewan, Canada.

READER IN HUMAN NUTRITION—The Staff Officer, University of Surrey, Battersea Park Road, London, S.W.11.

RESEARCH FELLOW (chemist and physicist with research experience) IN THE DEPARTMENT OF INORGANIC AND STRUCTURAL CHEMISTRY for work on high-pressure chemistry, mainly on the solid state—Dr. R. S. Bradley, School of Chemistry, The University, Leeds, 2.

RESEARCH OFFICER (with a Ph.D. degree or equivalent research experience in polysaccharide chemistry) to undertake full-time research on the structure and metabolism of polysaccharides of tropical pasture legumes—The Warden, University College of Townsville, P.O. Box 999, Townsville, Queensland, Australia.

RESEARCH OFFICER (with a degree or equivalent qualification in chemistry or physics or electronics, and preferably experience in the maintenance, operation, and construction of scientific instruments) IN CHEMISTRY—The Registrar, University of Queensland, St. Lucia, Brisbane, Queensland, Australia.

RESEARCH TECHNICIAN (preferably with previous experience of histological and/or photographic techniques) for work on electron microscopy—Dr. R. M. Hardisty, Department of Haematology, Hospital for Sick Children, Great Ormond Street, London, W.C.1.

SCIENTIFIC INFORMATION OFFICER (with a degree in agriculture or related subjects and a flair for languages, including English) to join a team engaged in publishing the latest research findings on temperature and tropical grasslands and annual field crops in two journals of international repute—The Director, Commonwealth Bureau of Pastures and Field Crops, Hurley, near Maidenhead, Berkshire.

SENIOR TECHNICIAN IN THE DEPARTMENT OF CHEMISTRY to be responsible for the teaching and postgraduate laboratories and for a team of four technicians—The Staff Officer, University of Surrey, Battersea Park Road, London, S.W.11.

SENIOR TECHNICIAN (with considerable laboratory experience and preferably some experience of electronics and/or workshop practice) IN THE DEPARTMENT OF INORGANIC, PHYSICAL AND INDUSTRIAL CHEMISTRY, to assist in research projects using nuclear magnetic resonance and electron spin resonance techniques—The Registrar, The University, Liverpool, 3, quoting Ref. No. 315.

TECHNICIANS/JUNIOR TECHNICIANS (young men and women of 18 and over) in the general teaching laboratories and physical chemistry laboratories in the Department of Chemistry—The Staff Officer, University of Surrey, Battersea Park Road, London, S.W.11.

## REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

### Great Britain and Ireland

# DYES...?

## EDWARD GURR LTD. 'MICHROME'

### STAINS AND REAGENTS FOR MICROSCOPY, DYES FOR SCIENTIFIC, PHARMACEUTICAL & TECHNOLOGICAL PURPOSES

Over 3,000 currently available, including:

Amido black 10B, Aquamount, Canada balsam, Biebrich scarlet BPC, celloidin, crystal violet BPC, DPX mountant, euchrysins 2GNX & 3R, Fluormount, Fluorol, Janus green, Jenner stain, Laktoseal, Lipid crimson, Luxol fast blue, LVN (low viscosity nitrocellulose), malt extract, bact., Matamount, maxilon blue RL, May-Grunwald stain, mercury orange, p-ethoxychrysoidin, methyl green, methyl red, methylene green, naphthalene violet, naphthochrome green, Naphthols (substituted), neococcine, neutral violet, neutral red, new fuchsin, night blue, Nile blue, nitrazine yellow, nitrotetrazolium blue, nuclear fast red, nuclear fast red salt, oil blue N, Optoil, paraldehyde fuchsin, pararosaniline, peptones, phloxin, pinacryptol yellow, protargol, RSR reagent, rosolic acid, Sienna orange, Scarlet, R, BPC, Nuclear fast red for calcium, Sudan black, toluidine blue, Trifalgic acid, Uvak, Wright's stain, p-xenol blue, yeast extract (bact.), etc.

### ★ PANICOLAOU STAINS; SHORR, MF4 and KH STAINS; ACRIDINE ORANGE For Exfoliative Cytology, etc.

★ Information leaflet A4 ("Notes on Stains and Staining Methods in Diagnostic Cytology as applied to Cervical and Vaginal Smears" by Edward Gurr) available gratis on request.

### A NEW AND UNIQUE DIAGNOSTIC AGENT

## \*FALG STAIN

(B. T. Squires' modification)

with many indications including the detection of  
PROTEIN-CALORIE DEFICIENCY  
STATE OF HEALTH IN MAN AND ANIMALS  
MALINGERING,  
etc.

\*Descriptive pamphlets and catalogue available on request.

## \*RHODANILE BLUE

An entirely new type of basic dye conceived and synthesized for the first time by Dr. Edward Gurr with the object of providing a new research tool. This unique polychrome dye possesses interesting and unusual properties. It has been found to have a number of very useful applications both in polarized and ordinary light microscopy; for example, it provides a distinctive stain for fibrin.

Recent books by Dr. Edward Gurr,

RATIONAL USE OF DYES IN BIOLOGY (1965), 422 pp.  
Roy. 8vo., 105/-.

STAINING, Practical and Theoretical (1962), 637 pp., 95/-  
ENCYCLOPAEDIA OF MICROSCOPIC STAINS, (1960),

Uniform High Quality, Service, Reliability  
and Immediate Delivery

## An Introduction to Magneto-Fluid Mechanics

V. C. A. FERRARO and  
C. PLUMPTON

The scope of this enlarged edition remains the same as before, namely, a text intended as an introduction for research workers in the fields of magneto-hydrodynamics and plasma physics, which will also be found suitable for third-year undergraduates studying these topics. *Second edition, 2 plates, numerous text figures 50s net paper covers, 25s net*

## Infra-Red Physics

J. T. HOUGHTON and  
S. D. SMITH

A book designed for final-year undergraduates in physics or chemical physics and young research workers. Quantum mechanics is applied to the interaction of radiation with molecular and crystal systems, and an account is given of molecular and solid-state spectroscopy that illustrates basic processes. *60s net*

## General Protozoology

V. A. DOGIEL

*Revised by J. I. POLJANSKIJ and*

E. M. CHEJSIN

'It will prove invaluable to protozoologists and biologists in general. . . . Readers will find it stimulating and challenging. . . . The book is illustrated with . . . exceptional clarity and its references are thoroughly international.'

NATURE *Second edition (no previous edition in English), 326 text figures £7 7s net*

## The Mystery of Matter

*Edited by LOUISE B. YOUNG*

The readings in this collection centre on questions concerning the nature of the physical universe and life. Drawn from a wide range of sources, the selections include material from classical and modern science as well as articles from other areas such as philosophy and the social sciences. *Numerous text figures 70s net*

### Classified Advertisements

Semi-displayed £4 16s. per single column inch. Minimum £2, each additional 1/12th of an inch 8s. Full page £132. Half page across £66. Colour (orange) £15 extra. Is. is charged for the re-direction of replies to advertisements with a box number.

•ADVERTISEMENTS SHOULD BE ADDRESSED TO: T. G. Scott and Son, Limited, 1 Clement's Inn, Strand, London, W.C.2. Telephone: HOLborn 4743. Telegrams: Textualist, London, W.C.2.

### APPOINTMENTS VACANT

#### OPENING FOR ASSOCIATE DEAN (RESEARCH) ONTARIO VETERINARY COLLEGE UNIVERSITY OF GUELPH GUELPH, CANADA

A veterinarian with advanced training, and keen interest in the co-ordination of research with an academic programme, will be considered for the position of Associate Dean. The incumbent will be required to administer certain funds, to maintain liaison with agencies granting research support, and to negotiate in certain matters, on behalf of the College, with the Vice-President (Academic) of the University, the Vice-President (Administration), and with corresponding officers of various other agencies. The incumbent will serve as Acting Dean in the absence of the Dean, and will be directly responsible to him.

Applications and inquiries are invited no later than January 23, 1967. All correspondence should be addressed to the Dean, Ontario Veterinary College, University of Guelph, Guelph, Canada. (5)

#### UNIVERSITY OF QUEENSLAND UNIVERSITY COLLEGE OF TOWNSVILLE POST-DOCTORAL RESEARCH IN POLYSACCHARIDE CHEMISTRY

Applications are invited for the position of RESEARCH OFFICER to undertake full-time research on the structure and metabolism of polysaccharides of tropical pasture legumes. The successful applicant will work with a rapidly growing research group studying the polysaccharides of tropical flora and fauna under the general supervision of Professor G. N. Richards, and he will be given opportunity to participate in the supervision of research students on related topics. Good facilities for this type of research are now available in Townsville and close liaison is maintained with C.S.I.R.O. Tropical Pastures Division in this field. Applicants should hold a Ph.D. degree or have equivalent research experience in polysaccharide chemistry. Salary on the Research Officer Grade I scale will be \$A4,800 and some assistance with travel may be provided. The appointment is for 2 years if desired, and some remunerated teaching will be available if desired.

Letters of application, including details of research experience and names of three referees, should be forwarded to the Warden, University College of Townsville, P.O. Box 999, Townsville, Queensland, Australia. Possible applicants may also seek further details from Professor G. N. Richards at the same address. (9)

#### DEPARTMENT OF PHYSICS UNIVERSITY OF WINDSOR WINDSOR, ONTARIO, CANADA

Applications are invited for the following staff appointments:

1. EXPERIMENTAL PHYSICIST (Atomic Physics). Preference will be given to candidates with interests in atomic collision or optical pumping phenomena.

2. THEORETICAL PHYSICIST. Preference will be given to candidates with interests in one of the following fields: atomic collisions, solid state physics (E.S.R.), plasma physics, elementary particle physics with applications to astrophysical problems.

In each case the successful candidates will be expected to instruct in undergraduate and post-graduate courses and to devote a part of their time to research. The appointments may be made at the ranks of Assistant Professor, Associate Professor or Professor at which properly qualified candidates can expect salaries of not less than \$9,000, \$12,000 and \$15,000 per annum respectively.

Inquiries should be addressed to Dr. L. Krause, Head, Department of Physics. (X1)

## Scientific Civil Service

### RESEARCH FELLOWSHIPS

PRINCIPAL RESEARCH FELLOWSHIP between £2,250 and £3,105 annually. Tenable for 1 year to 3 years (with possibility of extension to 5 years).

SENIOR RESEARCH FELLOWSHIP between £1,745 and £2,155 annually.

JUNIOR RESEARCH FELLOWSHIP between £1,180 and £1,575 annually. Both tenable for 3 years.

### EXAMPLE OF CURRENT VACANCIES

#### MICROBIOLOGICAL RESEARCH ESTABLISHMENT, Porton Down, Nr. Salisbury, Wilts.

Applications invited from a Physical-chemist, biochemist or microbiologist to study macromolecular aspects of virus-antibody and/or virus-cell interaction with special reference to specificity and population heterogeneity. These studies lie in the area between biology and the "exact sciences", and a genuine interest in molecular-virology is more important than initial discipline. (Principal, Senior or Junior.)

Fellowships at this and other establishments are available in most of the scientific disciplines and successful candidates have considerable freedom of choice of their specific research topics. A good honours degree or an equivalent or higher qualification is normally required for all grades of Fellowship together with proof of research ability. A candidate for a Principal Fellowship must produce evidence (including published work) of a considerable period of fruitful research and be accepted as a leading worker in his or her field; the standard expected is similar to that required for the award of a D.Sc. degree. Candidates for Senior or Junior Fellowships must have successfully performed, respectively, at least three or two years' post-graduate research during which a high standard of research ability must have been demonstrated.

F.S.S.U. terms. Enquiries, which need not be confined to the above example, to Civil Service Commission, Savile Row, London W.1, stating age and qualifications and quoting S/570.

## MINISTRY OF TECHNOLOGY

#### LABORATORY OF THE GOVERNMENT CHEMIST Stamford Street, London S.E.1.

SENIOR SCIENTIFIC OFFICERS/SCIENTIFIC OFFICERS for research and development in disciplines of technological and public health importance, e.g., on foods, drugs, steroids, vitamins, textiles, antibiotics, pesticides, fertilizers, waters etc., and in all branches of analytical chemistry, including microbiology and radiochemistry. The Laboratory is equipped with the most modern physical instrumentation including a fragment mass spectrometer and a 400 channel gamma spectrometer.

QUALIFICATIONS: 1st or 2nd class honours degree, Dip.Tech., or equivalent or higher qualification in appropriate subject and, for S.S.O., at least 3 years' post-graduate experience.

SALARY: S.O. £996 to £1,659.

S.S.O. (minimum age 26) £1,829 to £2,240.

Prospects of permanent pensionable appointments.

APPLICATION FORMS from the Government Chemist at the above address quoting E/AR/031.

(38)

#### UNIVERSITY OF LIVERPOOL

Applications are invited for the post of LECTURER or ASSISTANT LECTURER in Mathematical Statistics in the Department of Computational and Statistical Science. The initial salary will be within the range £1,105 to £2,095 per annum according to qualifications and experience.

Applications, stating age, qualifications and experience, together with the names of three referees, should be received not later than January 21, 1967, by the Registrar, Liverpool University, Liverpool 3, from whom further particulars may be obtained. (Please quote Ref. 336). (51)

#### UNIVERSITY OF YORK

##### DEPARTMENT OF MATHEMATICS

Applications are invited for posts as LECTURER (on the scale £1,470 to £2,630) or Assistant Lecturer (on the scale £1,105 to £1,340) in Pure Mathematics from October 1, 1967. For one of these posts, preference will be given to applications from candidates whose research interest is in Analysis.

Four copies of applications, naming three referees, should be sent by January 27, 1967, to the Registrar, University of York, Heslington, York, from whom further particulars may be obtained. (69)

# FOREST RESEARCH

Department of Forestry and Rural Development  
VARIOUS CENTRES ACROSS CANADA

## Interviews in the United Kingdom and Ireland

Interviews with departmental scientists may be arranged at any of the following centres during the period  
February 27—March 14, 1967 :

**LONDON — BIRMINGHAM — LIVERPOOL — GLASGOW — DUBLIN**

If interested, write immediately (air mail) to the address below enclosing a brief description of your training and interests and indicate your choice of an interview centre. You are assured of a prompt reply which will specify the time and place of your interview at the centre of your choice.

**STAFFING BRANCH  
CIVIL SERVICE COMMISSION  
OTTAWA 4, ONTARIO, CANADA**

Attention : R. K. Cox—Bio-Physical Sciences Program.

(57)

### UNIVERSITY OF EAST AFRICA UNIVERSITY COLLEGE, DAR ES SALAAM

Applications are invited for a LECTURESHIP IN CHEMISTRY (Organic, Physical, or Inorganic). Post vacant from June, 1967. Salary scale (including expatriation allowance) £1,550 to £2,350 per annum, plus 12½ per cent interim award on basic salary scale. Permanent terms or contract terms carrying 25 per cent gratuity (15 per cent if in F.S.S.U.). Subsidized housing. Expatriates receive: education allowances; family passages; biennial overseas leave. Salary and terms of service under review.

Detailed applications (6 copies), naming 3 referees, by February 9, 1967, to Inter-University Council, 33 Bedford Place, London, W.C.1, from whom particulars are available. (39)

### UNIVERSITY OF ADELAIDE

Applications are invited for the following appointments, the closing dates for applications being stated in brackets after each post:

**READER AND SENIOR LECTURER IN MATHEMATICS** (Pure Mathematics; preference for at least one post to candidates with interest in general field of algebra). (January 16, 1967.)

**SENIOR LECTURER IN HUMAN PHYSIOLOGY**, with preference to a candidate with a medical qualification and a higher degree (January 16, 1967).

**LECTURER IN ARCHITECTURE** (January 31, 1967).

**LECTURER IN MATHEMATICAL PHYSICS**, with preference to candidates with interests in theoretical nuclear or elementary particle physics (February 15, 1967).

**LECTURER IN COMPUTING SCIENCE**, with preference to applicants experienced in numerical analysis, operations research, and/or theory of automatic systems (January 31, 1967).

**SALARIES**: Reader, £A8,600 a year; Senior Lecturer, £A6,500 by £A220 to £A7,600; Lecturer, £A4,800 by £A220 to £A6,340; with superannuation on the F.S.S.U. basis.

A STATEMENT giving full particulars about each post and the conditions of appointment, and any other information sought, will be supplied on request to the Registrar of the University or to the Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1.

APPLICATIONS should be sent, in duplicate and giving information listed in the statement that will be supplied, to the Registrar, The University of Adelaide, North Terrace, Adelaide, South Australia. (27)

**Harwell**

A Physicist is required  
for work in

## RADIOLOGICAL PROTECTION

A Physicist is required by Harwell's Health Physics and Medical Division to join their Health Physics Operations organization. After a period of training, the successful candidate may expect to take charge of an operational team as an Area Health Physicist working in one of the AERE reactor or nuclear physics areas.

Area Health Physicists are responsible for advising experimental scientists, reactor and machine designers and operators on the short and long-term radiological protection aspects of their work. They supervise staff carrying out routine and special health monitoring duties as well as a programme of investigations aimed at improving protection techniques of particular interest to the area to which they are assigned.

The work calls for a sound knowledge of physics and an interest in reactors and nuclear physics machines but experience with radioactive materials is not essential as appropriate training will be given to the successful applicant. Applicants should preferably have a degree (or equivalent) but the minimum qualifications are G.C.E. in five subjects (including English Language at 'O' level and two scientific subjects at 'A' level). The starting salary will be within the range £735 to £1,860 according to age and experience.

Please apply to: Personnel Department 'A' (A517334)  
A.E.R.E., Harwell,  
Didcot, Berks.

(64)

**ROCHE**

## ORGANIC CHEMIST

We have a vacancy in the chemical laboratories of our Research Department at Welwyn Garden City for a young man with a Ph.D. He will be a member of a research team working in the field of synthetic organic chemistry. We are a member of one of the world's largest groups of ethical pharmaceutical and chemical companies. Conditions of service are very good.

Write in confidence to the Staff Officer at:

**ROCHE PRODUCTS LIMITED**  
15 MANCHESTER SQUARE LONDON W1

## FOREST ENTOMOLOGISTS AND TOXICOLOGISTS

DEPARTMENT OF FORESTRY  
VARIOUS CENTRES ACROSS CANADA

A number of entomologists are needed to meet the requirements of a rapidly growing forest research organization. Current opportunities are for scientists trained in insect cytology, genetics, physiology, ecology and toxicology (which includes basic studies on insecticidal residues and the mode of action of systemic insecticides).

Candidates should have an advanced degree and related experience. Opportunities for salary advancement are excellent.

Résumés should be submitted to the  
Civil Service Commission, Ottawa 4, Canada,  
quoting file reference 66-100-DF. Interviews may  
be arranged in the U.K. for February-March, 1967.

(56)

## SCIENCE SPECIALISTS

NATIONAL AGRICULTURAL ADVISORY SERVICE  
MINISTRY OF AGRICULTURE, FISHERIES AND FOOD

At least 20 posts for Chemists and Biologists to work as specialist advisers in animal nutrition, bacteriology, plant pathology, and soil science, and 2 posts for Analysts concerned with the testing of soil, feeding-stuffs, plant and other materials. Appointment to (i) Grade III or (ii) Grade IV according to age, qualifications, and experience.

Age: at least 26 for (i) or at least 20 for (ii).

**QUALIFICATIONS:** degree (or equivalent or higher qualification) in an appropriate agricultural or natural science. In addition for Grade III posts normally at least three years' further study or research and/or employment providing experience of equivalent value.

**FINAL YEAR STUDENTS MAY APPLY.**

**SALARY (national):** Grade III £1,396 to £2,193; Grade IV £899 to £1,277. Starting salary may be above minimum in both cases. Non-contributory pension. Promotion prospects.

**WRITE** to Civil Service Commission, Savile Row, London W.1, for application form, quoting 296/67. Closing date January 25, 1967.

(42)

## UNIVERSITY OF CAPE TOWN/ PROVINCIAL ADMINISTRATION OF THE CAPE OF GOOD HOPE

LECTURER (REGISTRAR) IN ANATOMY

Applications are invited from medical graduates for the post of Lecturer (Registrar) in Anatomy. The successful candidate will be required to participate in the teaching of anatomy to medical and medical auxiliary students. This post will fall under the joint University Provincial Medical Service, with University conditions of service. The salary scale is R.2,400 to R.2,760 to R.3,120 to R.3,360 to R.3,900 by R.150 to R.4,500 per annum. (Rate of exchange: R.2=£1.) Applicants should state their age, qualifications and experience. The names of two referees whom the University may consult should be given. The successful applicant should be available to assume duty on April 1, 1967, or as soon as possible thereafter.

Two copies of the application and testimonials should reach the Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (from whom memoranda giving the general conditions of appointment, travel allowance on appointment, and further information about the work of the department should be obtained), not later than February 10, 1967. A third copy of the application should be sent directly by airmail to the Registrar, University of Cape Town, Private Bag, Rondebosch, Cape Town, South Africa, by the same date. The University reserves the right to appoint a person other than one of the applicants or else to make no appointment. (36)

## UNIVERSITY OF CAPE TOWN LECTURER IN ZOOLOGY

Applications are invited for the post of Lecturer tenable on July 1, 1967. The appointment will be made according to qualifications and experience on the salary scale R.3,500 by R.150 to R.4,700 to R.4,800 per annum (R.2=£1). The successful applicant will be required to give instruction in invertebrate zoology at undergraduate and postgraduate levels. He will also be encouraged to undertake research, and good facilities for marine work are available.

Two copies of the application and testimonials should reach the Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (from whom memoranda giving the general conditions of appointment, travel allowance on appointment, and further information about the work of the department should be obtained), not later than March 1, 1967. A third copy of the application should be sent direct by airmail to the Registrar, University of Cape Town, Private Bag, Rondebosch, Cape Town, South Africa, by the same date. The University reserves the right to appoint a person other than one of the applicants or else to make no appointment. (37)

## AHMADU BELLO UNIVERSITY NORTHERN NIGERIA

Applications are invited for post of (a) SUPER-INTENDING TECHNICIAN or (b) SENIOR TECHNICIAN in Department of Civil Engineering. Applicants should be experienced in laboratory and workshop practice and supervision, and capable of detail design work and the manufacture and maintenance of laboratory equipment. Appointee will be required to instruct students in workshop techniques and train junior staff. Salary scales: (a) £1,450 to £1,600 per annum; (b) £1,050 to £1,400 per annum; 20 per cent supplementation basic salaries (generally free of income tax) payable to U.K. staff. Appointments tenable: (i) on fixed terms not exceeding 4 years with annual leave passages, or (ii) to retiring age with biennial leave passages. Return family passages, children's, car and initial appointment allowances; superannuation; subsidized accommodation.

Detailed applications (6 copies), naming 3 referees, by January 31, 1967, to Inter-University Council, 33 Bedford Place, London, W.C.1, from whom particulars are obtainable. (40)

## UNIVERSITY OF LEEDS DEPARTMENT OF MATHEMATICS

Applications are invited from suitably qualified applicants for posts of LECTURER OR ASSISTANT LECTURER in APPLIED MATHEMATICS in the Department of Mathematics. Special preference will be given to candidates working in the fields of mathematical physics, astrophysics, or control theory. Salary on the scale £1,105 to £1,340 for an Assistant Lecturer or £1,470 to £2,630 for a Lecturer.

Applications (three copies), stating age, qualifications and experience, and naming three referees, should reach the Registrar, The University, Leeds, 2, not later than January 16, 1967. (109)

***Histokinette***

**stays on the job**

**Histokinette  
special features  
include :-**

- Up to 24 hours delayed start
- Double processing capacity
- One or more motor members and baskets
- Unbreakable tissue basket and containers

Diagnostic reports to hand hours earlier than they would be with manual processing and in far greater numbers—the release of a valuable technician for other duties... these are the outstanding advantages of the Histokinette Automatic Tissue Processing machine. Once the Histokinette has been put into operation, it will *without supervision* go through the entire cycle of fixation, dehydration, impregnation in wax, or alternatively can be set up for the washing or staining of tissues. It can handle large numbers of specimens at the same time and while staff is off duty—speed up almost any technique by ensuring quicker and more thorough penetration by reagents.

A 24-hour clock is fitted as standard. Change over to 1 hour, 72 hour, or 7 day cycles (the latter of great value in double embedding and bone decalcification techniques) is simple and rapid.

***Hendrey***

## JOHN DEWEY'S GHOST

THE Plowden Committee on Primary Education has unfortunately produced a report which is more a textbook than a social document (*Children and the Primary Schools*, H.M.S.O., £1 5s.). On a number of important issues, the report is sensible and even adventurous, but its force is blunted by a web of exhortation and advice about the handling of the different parts of the primary school curriculum. It is also suffused with the attitude towards the education of the very young which has become characteristic of primary schools in Britain and elsewhere ever since the belated recognition half a century ago that even young schoolchildren must be treated as if they were real people. Of course they must—and it is high time that an influential authority should at last have said that corporal punishment must be forbidden in schools. It is also right that the examination used at eleven to channel children into different forms of secondary education should be discredited, for it is unnecessary as well as unjust. But does it follow that primary teachers should be as unconcerned as they are with what might be the intellectual consequences of their teaching? If it had wished to, the Plowden Committee might have asked whether the contemporary ethos of the primary school, humane though it may be, is a sufficiently tangible framework on which to build an educational process.

None of this detracts from the scheme the committee has devised for spreading the social benefits of primary education more equitably about the United Kingdom. There is now plenty of evidence that children from poor home environments are less likely to profit from the time they spend in school than children from better backgrounds. It follows that the best way of implementing the old slogan "equality of opportunity" is to see that children from poor environments are provided with better facilities at the schools they attend—better buildings, more teachers and more equipment. The Plowden Committee has had the courage to accept this principle, which is entirely to its credit. In doing so, it has designed a British alternative for schemes being tried elsewhere—the educational parts of the Poverty Program in the United States, for example. The committee proposes that local authorities should be encouraged to single out those of their schools at which children suffer from special social handicaps, and that they should then receive special help from public funds, partly so as to enable them to pay teachers better salaries. It remains to be seen whether the Government will make these funds available (as it should) and whether they will filter efficiently through the tortuous procedures that will no doubt be devised to see that public money is fairly spent. It might even now be wiser to devise a more rapid if less precisely equitable scheme for channelling

money to poor areas of the country. But the principle is sound, and should promptly be accepted.

The Plowden Report is also sound in its conclusion that there should be a more generous provision of nursery schools for children under five. Here, too, the case rests principally on social arguments, and is the now familiar springboard for schemes such as "Operation Headstart" in the United States. Educational stimulation at an early age is one way of helping children to liberate themselves from unfavourable backgrounds. There should be more of it. (With all this enlightenment, it is odd that the committee should be as complacent as it is about the psychiatric services for the primary schools.) On in-service training for teachers, the committee takes an entirely proper line, and even puts on record what many educationists have been saying for years—that every teacher should have an opportunity for intellectual refreshment at least once every five years. But is this enough? It is disappointing that the Plowden Committee has not made more of the schemes being tried out by a number of local authorities for giving primary teachers continuing help in certain fields, particularly in languages, mathematics and science. The committee will also have provided the British Government with a measure of support in its running battle with the teachers' unions by declaring that there is a need for more ancillary helpers in the schools, but its attempt to argue that the age of transfer from primary schools to secondary schools should be shifted from eleven to twelve is so much like an attempt to count the angels on the point of a needle that this issue will be thoroughly confused for years to come. That the committee should have made such heavy weather of this point is not, of course, a great surprise, given its confusion about the objectives of primary education.

Properly enough, the committee fought shy of some of the more obvious platitudes, but it describes the ideal school as a "community in which children learn to live first and foremost as children and not as future adults". To the extent that this formula encourages flexibility in primary schools, it is entirely admirable. Obviously the old pattern of primary education in which children of quite tender ages were regimented as if they were being put through a course of Pavlovian conditioning is thoroughly bad. But the ideal which the Plowden Committee has re-defined is also a licence for much that is shoddy in current teaching practice. All too often the assumption that there is a child's world distinct from that of adults allows primary school teachers to temper the rigours of the real world with the commendation of pointless effort. But, in reality, children would gain a great deal from a more open acknowledgment of the continuity between the

worlds which children and adults occupy. Even the Plowden Committee is pleased with the way in which the earlier acquisition of reading skills in British primary schools has made it possible for young children to participate at an early age in the adult practice of leisured reading. Many of the new mathematics programmes for young children have been consciously designed to give them a more mature appreciation of difficult matters without violating the well intentioned informality of the primary school. It is a great pity that the Plowden Committee has not followed its admirable definition of social goals by a more thorough search for intellectual goals as well. The progressive style of primary education for which John Dewey acted as an inspired impresario is better than what went before, but its practitioners are uncommonly smug in their conviction that knowing how to teach is more important than knowing what.

## DOOMSDAY 1967

THE British Broadcasting Corporation has an enviable reputation for the sober and honest treatment of scientific subjects on television, so that there was some surprise last week that the corporation should have welcomed the New Year with a programme called "Challenge" designed as if to draw attention to the catastrophe there will be if something is not done to call a halt to the spread of science and technology. With perverse thoroughness, the programme vividly delineated the problems occasioned by the introduction of new techniques of all kinds. Air pollution and water pollution were fully dealt with, as was fall-out. The emergence of strains of bacteria resistant to antibiotics was held up as a danger. The toll of human life on modern highway systems was well covered, as were several of the consequences of the rapidly growing population of the world. Tales were told of how it might one day be possible to use molecular biology for doing strange things with "the nature of life itself", and there was the worry about who should be given kidney machines and who should be left without. Altogether it was a performance to keep people awake at nights. It is no wonder that one of the participants reports a young married couple of his acquaintance to have resolved not to have children of their own. Unfortunately there is no reason to suspect that the programme was intended as a subtle means of solving what is called the population problem, so that its producers are not entitled to much credit on that account.

Indeed, they are entitled to no credit at all, for they seem to have fallen into the old doomsday fallacy which has been claiming social commentators as victims at least since the invention of gunpowder. It is easy and it is also tempting to let the mind dwell on the problems which change occasions. No doubt there were even Palaeolithic Cassandras who complained that some essential quality of primitive life would be lost if people settled down to keeping domestic animals and

growing crops (and there may be people now who say those ancient forebodings were correct). As things are now, with innovations of all kinds following each other in quick succession, the opportunities for gloomy prediction have multiplied enormously. But so, too, have the opportunities for avoiding disaster. Certainly it is wrong to make a fuss about the potential hazards of resistant micro-organisms without balancing this with an appreciation of the diminishing hazards of infectious diseases. It is equally misguided to forget that pollution in rivers may frequently be caused by the fertilizer plants upon which, in part, the survival of badly nourished people may depend. And wild talk about the potential hazards to society which may spring from recent work in biology is often simply wicked. The real problem is to find some way of balancing the benefits of change against the nuisances which change may often bring, or to find some way of eliminating the nuisances. The doomsday view does not help but, rather, hinders. It is no accident that petrified is often used as a synonym for frightened.

## FORWARD PLANNING

THE National Research Council in Canada has broken new and even unfamiliar ground in the planning of research by producing detailed forward forecasts of the resources of various kinds—people as well as money—that would be employed on university research for a decade or more ahead. First attempts in this direction were made in 1963 and, encouraged by the reception of its first forecasts, the National Research Council embarked on a more elaborate survey to use as the basis of a forward prediction, eventually published towards the end of 1966 (*Expenditures on Research in Science and Engineering at Canadian Universities*, NRC 9196, Ottawa, \$1.00). At this stage the greatest interest of the exercise will be the fact that the Forecasting Committee should have embarked on it at all. Nobody will seek to hold it too rigorously to the forecasts which have actually been made, particularly at the end of a decade in which there has been a four-fold increase in the enrolment of students at Canadian universities (where there are now more than 200,000 students), and when graduate enrolment is apparently increasing at something like 20 per cent a year. Yet the actual forecasts have a conservative flavour, perhaps because they have been compiled from the individual forecasts of universities which are accustomed, in the nature of things, to suspect that rapid change cannot continue indefinitely. Even so, total expenditure on university research in Canada may increase five-fold by 1975, from more than \$60 million a year to \$322 million a decade hence. Most of this growth is attributed to increases in the numbers of people engaged on research, both faculty members and students. The increasing cost of keeping one man fully occupied on research seems to be less worrying in Canada than it is elsewhere. It will be interesting to see how this balance shifts with time.

## NEWS AND VIEWS

### Computers Go Home?

THE decision by Bull-General Electric to withdraw from the market two computers designed and built by Machines Bull in France is likely to stiffen resistance to the involvement of American companies in French industry. General Electric obtained a half share in Machines Bull in 1964, and owns 51 per cent of the marketing organization, while the French concern owns 51 per cent of the manufacturing concern. The computers withdrawn are the Gamma 140 and 145, machines designed and built in France, but overlapping with the General Electric 400 series. General Electric says that the very large GE 600 machine, designed for use by a large number of people on a time sharing basis, is still for sale, although considerable disappointment with its performance has been expressed, and some orders cancelled. General Electric also has a foothold in the British market, through De La Rue-Bull Machines, of which 50 per cent is owned by Bull-General Electric, 25 per cent by the De La Rue Company and 25 per cent by General Electric. The computers cancelled were never part of the range sold by De La Rue-Bull in the United Kingdom, and the company has been at pains to point out that their range remains unchanged.

The cancellation is likely to confirm some French prejudices about the influence of American investment in Europe. Computer engineers certainly consider that the attitude of General Electric towards the British and French employees has been unsentimental even by the standards of computer companies who tend to hire and fire staff as the need for software waxes and wanes. The French *Plan Calcul*, which entered a new phase last month with the creation of the Compagnie Internationale d'Informatique, is hardly likely to founder as a result of the cancellations; indeed, it may well be strengthened by what will be interpreted as new evidence of American technological control. The new company, financed by the French Government, is to develop and construct a range of computers able to compete with the American machines; to do this, if it is possible, is likely to cost considerably more than the £50 m. which the French Government has so far decided to spend. Bitter about the General Electric decision, French computer engineers are likely to be making just this point.

### Contaminated Lead

It is becoming increasingly difficult for users of extremely sensitive counters to shield them from extraneous radiation. The problem is that some of the traditional materials used for shielding tend themselves to be contaminated. British steel, for instance, is likely to contain cobalt-60, and ruthenium-103 and -106. Cobalt-60 is introduced in the lining of blast furnaces as a means of checking the wear of the refractory bricks, and both ruthenium isotopes come from radioactive fall-out. One answer, which sounds facetious but is in fact quite serious, is to buy armour plate from old battleships built before the days of

fall-out and radio-tracer techniques. Another, adopted by a Swiss scientist, is to buy old railway lines and have them machined to fit together as a shield. Either course is likely to be very expensive.

The problem now seems to be spreading to lead, a common shielding material. Recently Mr. E. Reynolds of the Fisheries Radiobiological Laboratory reported that lead bricks bought to shield a scintillation counter were contaminated with silver-110 (*Nature*, **210**, 615; 1966), and Dr. J. Rundo of the Medical Physics Department at Harwell has found lead contaminated with antimony-125. Such contamination greatly increases the background levels and reduces the sensitivity of the apparatus, as well as confusing the issue by introducing a background level which continually decreases.

In both cases the source of contamination remains a mystery. One possibility is that there may be a link between the lead Mr. Reynolds has been using and a dismantled reactor—possibly the Merlin reactor, which was owned by Associated Electrical Industries and was demolished at the end of 1963. The Report of the Government Chemist for 1964 showed that the lead from a reactor contained silver-110. The demolition work at Aldermaston was supervised by the Nuclear Inspectorate of the Ministry of Power, which claims that it is very unlikely that any contaminated lead found its way on to the market. On the other hand, Mr. R. J. Philips, the Chief Designer of Graviners of Gosport (who supplied the bricks), believes it to be quite possible. The period between the demolition of Merlin and the discovery of the contamination is long compared with the half-life of silver-110 (270 days), which tends to argue against the reactor being the source of the contaminated lead. Another possible origin for the isotope suggested by Mr. Reynolds is its use by a mining company as a tracer to investigate the efficiency of extraction procedures, but nobody knows of a mining company using such a technique.

The origin of the antimony-125 in Dr. Rundo's lead seems equally obscure. Almost all lead contains antimony to improve its mechanical properties, but how a radioisotope was introduced cannot be explained. Add to this the fact that krypton from the atmosphere can no longer be used in proportional counters because it is contaminated with krypton-85, which has a half-life of ten years, and the magnitude of the problem becomes apparent. Neon must be used; it is less effective, but uncontaminated.

### Fall-out in New Zealand

ANXIETY in New Zealand about the French nuclear weapon testing programme in the Tuamotu Archipelago should be dispelled by a recent report to the Prime Minister. The report, by the directors of the Meteorological Service, the Institute of Nuclear Sciences and the National Radiation Laboratory, concludes that the French tests will add fractionally but not significantly to the long-lived radioactivity in New Zealand, and that the general level of radioactive contamination in the Southern Hemisphere will remain below that in the Northern Hemisphere. The total accumulation of strontium-90 from rain, for example, is more than four times greater in New York City than in New Zealand.

Continuous monitoring of fall-out in New Zealand since 1959 has indeed shown that the contamination of rain by strontium-90 since the late fifties increased until the end of 1964 much as in the Northern Hemisphere. Since then there has been a gradual decline of contamination with the disappearance of debris from nuclear weapons from the stratosphere, and the French tests have so far added very little in the way of long-lived material to the contamination being detected. In retrospect, it is remarkable how the deposition of radio-strontium in New Zealand has followed that in the Northern Hemisphere, though with a time lag and with a peak that never reached the same heights. No doubt the immediate consequences of the recent explosions in China will be less in the Southern Hemisphere than in the Northern.

## Cool Appraisal

SUPERCONDUCTORS have seemed for some time to offer attractive possibilities in power cables and transformers. It is argued that the greatly increased conductivity of cooled conductors or superconductors will more than make up for the cost of keeping them cool. Dr. K. J. R. Wilkinson, of the Central Research Laboratories of Associated Electrical Industries, has now carried out an investigation of the economic and technical feasibility of the idea (*Proc. Inst. Elec. Eng.*, **113**, 1509; 1966) which is likely to moderate some enthusiasm for superconductors.

Dr. Wilkinson has compared the use of niobium at 4° K (a superconductor), aluminium at 20° K (with a resistivity of  $3 \cdot 10^{-9}$  ohm/cm) and beryllium at 77° K (with a resistivity of  $2 \cdot 10^{-8}$  ohm/cm). His basic design uses two concentric annular cooling jackets with an evacuated space between them containing two radiation shields. For the extreme case of niobium at 4° K, Dr. Wilkinson shows that it will be more efficient to use several coolants for providing refrigeration, with the temperature dropping in smaller stages. The conductor would be in the form of a cylinder of niobium foil, with liquid helium circulating internally and liquid hydrogen and liquid nitrogen circulating externally. For the aluminium and beryllium conductors this design would be inadequate, and a wire stranded design is suggested.

Unfortunately, there seems little hope that the designs will ever be more than an academic exercise. The cost comparisons which Dr. Wilkinson makes show that only the niobium superconductor could be expected to offset its refrigeration costs by savings in conductor material and conduction losses. In this case, cost for a 3 phase circuit rated 760 MVA at 275 kV and 1,600 A would be about £12,000/km, against £13,000/km for copper, but this takes no account of construction and laying costs, which would certainly be enormously increased. For aluminium and beryllium the costs are much greater and work out at £24,000/km and £800,000/km respectively. In addition to the cost disadvantage, cooled cables are very vulnerable both to accidental damage and to fault overloads, and liquid hydrogen would represent a real hazard. For transformers the situation seems hardly more optimistic; although transformers wound with aluminium foil at 20° K might show a marginal advantage, this would be more than absorbed by the expenses of

installing, housing and supervising the plant, and looking after the liquid hydrogen.

## Directory of Directorates

UNESCO has produced the first volume of a series intended to be a much enlarged revision of the *Directory of National Science Research Councils* first published ten years ago. The first volume of the new series deals with Europe and North America (*World Directory of National Science Policy-Making Bodies, Vol. 1, Europe and North America*, Francis Hodgson, Ltd., £3 5s.). Later volumes will appear in the next few months. The intention is to include in the volumes those organizations which have a national responsibility for policy-making and the planning, organization and co-ordination of scientific and technological research. An attempt has been made to exclude bodies at "ministerial level" where they have responsibility not confined to planning and co-ordination of research, although clearly criteria for choice in this respect are bound to be exceedingly difficult to apply consistently.

## Mycoplasmas

from a Correspondent in Microbiology

THE Society for General Microbiology in conjunction with the Pathological Society held a timely and stimulating symposium on mycoplasmas in London last week. Papers on fine structure, antigenicity and identification provided a basis for a discussion of the pathogenicity of these microbes and their effects on animal cells. D. Taylor-Robinson proposed that identification schemes should consider the source of isolates—avian, mammalian, tissue culture, and the like—and metabolic attributes of isolates, such as glucose or arginine fermentation and their antigenic structure. Identifications based upon only a few criteria are clearly equivocal. Similarly, extreme caution should be exercised when interpreting electron micrographs purporting to demonstrate mycoplasma-like particles in malignant human tissues. (A warning to this effect was issued recently by the World Health Organization.) Another urgent problem in the study of mycoplasmas is the correct diagnosis of strains as the causal agents of disease. It is surprising and, indeed, disappointing that, in many reports of the isolation of mycoplasmas from disease conditions, these organisms are stated categorically to be the causative agents even though the crucial re-infection tests have not been made. In this context the investigation of swine enzootic pneumonia, described at the meeting by R. F. W. Goodwin and P. Whittlestone, is encouraging and exemplary. These workers obtained a number of mycoplasmas from pneumonic pigs only some of which would induce the disease when inoculated into healthy animals. The causal mycoplasma of the enzootic condition, *M. suis pneumoniae*, has very exacting growth requirements in comparison with other isolates. Thus the readily cultured and less fastidious types isolated from mixed mycoplasma populations may be wrongly identified as the pathogens, especially when the application of Koch's postulates is ignored.

Identification of causative factors is an acute problem in connexion with malignant and arthritic diseases.

Several reports have appeared on the association of mycoplasmas with neoplasms, but the significance of these associations is poorly understood. Some mycoplasmas have properties in common with tumour inducing viruses such as Rous sarcoma and polyoma. At the meeting, W. Russell discussed the transformation of *BHK21-C18* hamster fibroblast cells by mycoplasmas which closely resembled the transforming pattern of tumour viruses. In contrast to virus transformations, however, cells transformed by mycoplasmas showed no evidence of mycoplasma antigens or transplantation immunity, while tumour formation was not induced in hamsters inoculated with *M. fermentans*. Imbalanced nucleic acid metabolism in infected fibroblasts (see also Russell, W., *Nature*, **212**, 1537; 1966) might permit genetic changes which could produce neoplasms: such a role for mycoplasmas in oncogenesis is at present entirely speculative. In defining the current position on mycoplasmas and human leukaemias, R. J. Fallon concluded that there is no established cause and effect relationship even when mycoplasmal antibodies are associated with the leukaemic condition. The question of crypto-mycoplasmal infections not detected easily by ordinary culture methods may be significant here. The failure to isolate mycoplasmas from tissue cultures or rheumatoid synovial membranes probably reflects exacting nutritional requirements which would favour the establishment of obligate parasitism. The induction of, and the means of identifying, crypto-infections are important areas of investigation in attempting to elucidate the relationship, if any, of mycoplasmas to these types of diseases.

## Fluid Logic

SOME 360 delegates met at Cambridge last week at a conference on fluidics—the second of its kind to be held in Britain. The conference was organized by the British Hydromechanics Research Association in conjunction with the College of Aeronautics, the Institution of Mechanical Engineers, and the Society of Instrument Technology.

Fluidics is an abbreviation of the two words “fluid logic” and stands for one of the newest technological tools mainly concerned with small devices without mechanical parts in which, for example, flows can be switched by low pressure impulses, and in which small pressures can be amplified or compared so as to form the *and*, *or*, *nor* types of decisions. The technique offers a means of controlling processes and operations of devices which are insensitive to extremes of temperature, corrosion and the like, and which are also cheap and rugged. Many control problems are implicitly concerned with fluidics in any case, so that fluid logic is often a natural choice of a means of control, whether the fluid is sulphuric acid, radioactive liquid, burning gas, or simply air. Fluid logic devices have already been used successfully in the measurement of angular rate, high temperature, and also in controlling turbine speeds.

The fifty or so papers presented at the conference at Cambridge provided a comprehensive picture of what has happened since the first developments in fluidics seven years ago in the United States. Fundamental and industrial applications were dealt with in the

papers presented, and particular topics discussed included the application of fluidics to nuclear plant and machine tool operations of various kinds. It is encouraging that interest in fluidics has roughly doubled in the past 18 months, at least if interest is accurately reflected in the number of papers presented at the first and second conferences. The universities, the Ministry of Technology, the professional institutions and some sections of British industry are well aware of the challenge and the potential rewards of fluidics, but it is worrying that substantial sections of British industry are apparently unaware of the new technique.

## Ultra-centrifuge Anomalies

WHEN sedimentation and diffusion coefficients are calculated from ultra-centrifuge experiments, certain assumptions are usually made. Originally these were that there is a sharp free boundary between solvent and solute, that the ultra-centrifuge reaches a constant angular velocity immediately after starting and that the sedimentation and diffusion coefficients are independent of concentration. A solution due to Fujita and MacCosham used a realistic boundary condition instead of the sharp free boundary, and the assumption about instantaneous speed-up is incorporated by assuming the centrifuge to have started at an intermediate time equal to two-thirds of the time needed for acceleration. Speaking at a meeting of the physical biochemistry group of the British Biophysical Society, Dr. V. D. Barnett, of the University of Birmingham, suggested that even these modifications may not be enough to give consistent values for the coefficients.

Using an improved estimation procedure (based on a linearized least squares approach) which gives more accurate estimates of the coefficients, and calculating them for different times rather than for only one Schlieren frame, he had obtained estimates of the different coefficients of the process which showed an unexpected time-dependence. In an attempt to resolve this anomaly by relaxing the assumption of instantaneous starting, Professor H. E. Daniels, also of the University of Birmingham, has developed an expression in the form of a power series which describes the concentration gradient profile during the acceleration phase. Combining this with the solution for the profile after the switch-off in the constant angular velocity phase produces the solution for any general time. It is hoped that this modified solution will resolve the earlier anomalies, and data are being analysed to confirm this. In the discussion of Dr. Barnett's paper, some speakers expressed the fear that it may invalidate much previous work carried out with the ultra-centrifuge.

At the same meeting of the Biophysical Society, Dr. S. P. Spragg and Dr. R. F. Goodman, of the Department of Chemistry at Birmingham, discussed the problems associated with the acquisition of data from an ultra-centrifuge by an “on line” computer. Using an absorption technique, pulses are fed directly into the computer through a photo-multiplier, and are stored by the computer only when they are significantly different from the previous pulse. This means that the computer will only store useful information, and by pausing at certain points along the scan can improve the signal to noise ratio significantly.

## Transforming Communities

AGRONOMISTS and sociologists, sponsored by Shell International, have been helping the inhabitants of poor rural communities in Northern Italy, Nigeria, Venezuela and other parts of the world to increase their net income. Some of their work is described in the latest publication of the World Land Use Survey, *The Transformation of Rural Communities* (occasional papers No. 7).

Borgo a Mozzana is a *comune* (the smallest Italian administrative unit) in Tuscany. It has a population of 8,000 with about 1,300 small farms, mostly run by their owners, on poor acid soil. The main crops are cereals, olives, vines and potatoes; cattle are reared for veal and milk. An agronomist went to Borgo in 1954 and began to persuade farmers to improve their agricultural methods and materials. It was two years before he was fully accepted, but gradually new and better strains of crop plants, seeds and fertilizers were introduced. By 1963 the corn and wheat crops had increased, the quality of the vines had improved and the total value of oil produced had increased from 13 to 84 million lira.

A home economics adviser encouraged women of the community to improve child care and domestic hygiene. To improve the poultry, traditionally in the women's care, new breeds of fowls were introduced and a co-operative was formed for the organization of production and marketing of poultry and eggs. Such co-operation was the result of encouragement to the people to discuss their problems together. A consortium was formed for the production of seed potatoes in the hillside hamlet of Cune, and to make technical progress easier a road was built to link Cune with the centre of the *comune*.

In Southern Nigeria an agronomist and his assistant have begun to introduce pest control chemical fertilizers and better varieties of plants to the rural areas of Uboma. The oil palm, which is indigenous to Nigeria and is integrated into farming systems, has been improved as a cash crop, although it has proved difficult to convince farmers of the wisdom of marketing, which they tend to regard as "bad farming". Fish and poultry have been improved to increase the production of animal protein. Farmers have been organized into co-operatives based on religious or other groups; piped water has been supplied, and a health centre built.

In the Zulia district of Venezuela there is a project to improve the standard of agriculture which is based on family groups. Experts spent a year acquainting themselves with the area, and then began to demonstrate to the farmers how to improve their income from the land. Several new crops have been introduced, and weeds which have severely restricted crops in the past have been controlled, as have termites and ants.

The introduction of ploughs drawn by donkeys for fifty of the farmers has enabled the area of cultivation to be increased. Women and children have been encouraged to contribute with domestic trades, such as poultry rearing and bee keeping. The group working on this project consider that progress so far suggests that this will be a practical and relatively inexpensive way of promoting the transformation of traditional agriculture.

## University News :

## Aston in Birmingham

DR. W. O. ALEXANDER, at present technical director with Fosco International, has been appointed professor and head of the Department of Metallurgy.

## Appointments

DR. H. R. FLETCHER, Regius keeper of the Royal Botanic Gardens, Edinburgh, has been appointed Her Majesty's botanist in Scotland.

## Announcements

MR. E. GUDGEON, general sales manager, Harchem, Ltd., Toronto, has been elected chairman of the Chemical Economics Division of the Chemical Institute of Canada for 1967. He succeeds Lyall Fraser, of the United Shoe Machinery Co. of Canada, Ltd., Montreal.

At the annual general meeting of the Institution of Electronic and Radio Engineers on December 15 the following awards were presented for the outstanding papers published in the Institute's monthly journal, *The Radio and Electronic Engineer*, during 1965: *The Clerk Maxwell Premium* to Dr. G. O. Young for his paper, "Statistical Optimization of Antenna Processing Systems"; *The Mountbatten Award* and the *S. C. Bose Premium* to Professor S. K. Chatterjee and Mrs. R. Chatterjee for their paper, "Dielectric Loaded Waveguides—A Review of Theoretical Solutions"; *The Heinrich Hertz Premium* to J. S. Heeks, A. D. Woode and C. P. Sandbank for their paper, "The Mechanism and Device Applications of High Field Instabilities in Gallium Arsenide"; *The Lord Rutherford Award* to F. D. Boardman, E. L. E. Harrington and D. J. A. Carswell for their paper, "A Correlator for Investigating Random Fluctuations in Nuclear Power Reactors"; *The A. F. Bulgin Premium* to D. Harrison for his paper, "The Mechanism of Interference Pick-up in Cables and Electronic Equipment with special reference to Nuclear Power Stations"; *The Marconi Award* to J. Salomon, S. Pichafroy and P. Hurbain for their paper, "A Radar Receiving Array with I.F. Multiple-beam Forming Matrix"; *The Leslie McMichael Premium* to W. J. Battell for his paper, "An Analysis of Results obtained on an Aircraft Data Link out to 1,300 Nautical Miles (2,400 km)"; *The J. Langham Thompson Premium* to P. C. Young for his paper, "The Determination of the Parameters of a Dynamic Process"; *The Babbage Award* to P. I. Bonyhard and W. S. Carter for their paper, "Large Capacity Magnetic Film Stores—A Design Approach"; *The Dr. Norman Partridge Memorial Premium* to H. Lindskov Hansen for his paper, "A Groove Feed and Depth Control System for Gramophone Disk Cutting Equipment"; *The Rediffusion Television Premium* to F. G. Johannessen for his paper, "The Performance Requirements of a Television Monitor Receiver (Nyquist Demodulator) and Methods of Measurement".

THE 1966 Entomological Society of Canada Annual Gold Medal Award for outstanding achievement in Canadian entomology has been awarded to the late Dr. C. W. Farstad, who was director of the Plant Protection Division of the Canadian Department of Agriculture.

THE Paul Instrument Fund Committee, which is composed of representatives of the Royal Society, the Institute of Physics and the Physical Society and the Institution of Electrical Engineers, and was set up in 1945 "to receive applications from British subjects who are research workers in Great Britain for grants for the design, construction and maintenance of novel, unusual or much improved types of physical instruments and apparatus for investigations in pure or applied physical science", has made the following awards: Dr. R. D. DAVIES, senior lecturer in radioastronomy in the University of Manchester, £4,132 to enable him to extend from

120 to 192 the number of frequency channels on the spectrometer for radioastronomy using digital auto-correlation techniques; PROF. J. N. HUNT, professor of physiology, Guy's Hospital Medical School, £980 for the construction of a recording *in vivo* colorimeter; DR. W. J. JONES, University Chemical Laboratory, Cambridge, £500 for the purchase of equipment to enable him to increase the efficiency of the laser apparatus for the excitation of Raman spectra; DR. D. W. TURNER, reader in organic chemistry at the Imperial College of Science and Technology, London, £3,000 for the construction of a K-shell photoelectron spectrometer.

A NEW journal entitled *Chemical Physics Letters* is being published by North-Holland Publishing Company as from January this year. It will appear initially as a monthly journal and deal primarily with results of theoretical and experimental research in the field of chemical physics.

DR. B. C. J. LIEVEGOED, professor of social pedagogy at the Netherlands School of Economics and dean of the Faculty of Social Sciences in the new Twente Technological University Enschede, will give the first of the newly established Andrew Betts-Brown Memorial Lectures at Heriot-Watt University on January 16. The title of his lecture, which is open to the public, is "Consequences of Technological and Social Change".

THE eighth International Embryological Conference will be held in Interlaken during September 3-9. Further information can be obtained from Dr. A. Curtis, Zoology Department, University College, London, Gower Street, W.C.1.

AN international symposium on "Tropical Root Crops" is to be held in the University of the West Indies during April 2-8. Further information can be obtained from the Secretary, International Symposium on Tropical Root Crops, Department of Agriculture, Crop Production, University of the West Indies, St. Augustine, Trinidad.

A SYMPOSIUM on "Atomic Absorption Spectroscopy" is to be held in the Welsh College of Advanced Technology during April 6-7. Further information can be obtained from the Organizer of Short Courses, Welsh College of Advanced Technology, Cathays Park, Cardiff.

A ONE-DAY symposium on "Telemetry in Medical and Biological Research", organized by the Scottish Sections of the Institution of Electronic and Radio Engineers and the Institution of Electrical Engineers, will be held at the Royal Infirmary, Edinburgh, on March 9. Further information can be obtained from P. M. Elliott, Honorary Secretary, Scottish Section, I.E.R.E., 21 Craigmount Loan, Corstorphine, Edinburgh 12.

ERRATUM. In the communication by Dr. E. T. Gláz, E. Csányi and J. Gyimesi entitled "Supplementary Data on Crotoxin—an Antifungal Antibiotic" (*Nature*, 212, 617; 1966) the second sentence of the fourth paragraph should read "... the cytotoxic concentrations (in  $\mu\text{g}/\text{ml.}$ ) which resulted in 50 per cent inhibition of transplantability were as follows: crotoxin 400.0, crotoxin 250.0, trichothecin 20.0 and trichothecol (the alcohol part of trichothecin) 400.0".

CORRIGENDUM. In the communication "Renin and Euryhalinity in the Japanese Eel, *Anguilla japonica*" by Dr. H. Sokabe, Dr. S. Mizogami, Dr. T. Murase and Prof. F. Sakai (*Nature*, 212, 952; 1966), on line 4 "three to" should be inserted between "for" and "eleven", and on line 38 "of pH 7.4" should be inserted following "buffer".

CORRIGENDUM. In Table 1 of the article "Maternal Origin of the Group Specific (Gc) Proteins in Amniotic Fluid", by M. Usategui-Gomez and D. F. Morgan, in *Nature*, 212, 1600 (1966), in the column headed "Foetal sera" the sixth figure should be 2-1 and not 2-2.

## CORRESPONDENCE

### Origin of the Genetic Code

SIR,—I should like to make two points about the account of my talk to the British Biophysical Society which you published recently<sup>1</sup>. I do not in fact believe that the idea of a stereochemical relationship between all amino-acids and their anticodons, as suggested by Dunnill<sup>2</sup>, is likely. There is, in my opinion, suggestive evidence against it, but at the moment it is not enough to disprove the idea.

My second point concerns the main substance of my talk, which was an attempt to show that a plausible theory could be constructed without necessarily assuming any stereochemical interaction of amino-acids with either codons or anti-codons. I imagined the code to go through three phases:

1. The Primitive Code, in which a small number of amino-acids were coded by a small number of triplets.

2. The Intermediate Code, in which these primitive amino-acids took over most of the triplets of the code in order to reduce nonsense triplets to a minimum<sup>3</sup>. The codons produced by this process for any one amino-acid were likely to have been related.

Woese<sup>4</sup> has pointed out that this state of affairs could also have been produced by reading only a single base of a triplet, or by considerable inaccuracy in the reading of a few triplets.

3. The Final Code, as we have it today.

The crucial idea, already mentioned by Jukes<sup>5</sup>, concerns the transition from 2 to 3, which I certainly do not think was "unlikely to have taken place"<sup>1</sup>. Evolutionary theory suggests that a new amino-acid was incorporated into the developing code only if its introduction at that time gave a selective advantage to the primitive organism. This implies that its introduction did not disturb too much the proteins then being produced, and in addition made a significant improvement to at least one of them. This would have happened most easily if

- (a) the new amino-acid was "related" to the one previously coded by the triplet(s) in question<sup>6</sup>;
- (b) the organism coded rather few proteins;
- (c) these proteins were rather primitive in their construction.

Eventually as the number of proteins coded became larger, and their design more sophisticated, no possible new amino-acid could, on balance, be an advantage and the code would be frozen.

Such a theory could thus explain in a general way the non-random nature of the present code, since "related" amino-acids might well have acquired related codons. It is quite distinct from theories<sup>3,7</sup> which postulate that the code evolved as it did in order to minimize the damaging effects of present-day mutations on individual proteins.

# Foot-and-mouth Disease—a World Problem

by  
J. B. BROOKSBY

The Animal Virus Research Institute,  
Pirbright

In the past few days there has been some evidence of infection by foot-and-mouth disease among animals in the south of England. In Britain the disease is controlled by slaughtering infected animals. The difficulties of control by vaccines were described by Dr. Brooksby in a lecture to the Royal Veterinary College, London, on November 30, 1966, and the following article is an extract of his lecture

THE problem of foot-and-mouth disease is worldwide. The animal population over a large part of the land surface of the globe is already affected by it and, because of the extraordinary facility with which the virus spreads, no area can be considered safe. It is true that the disease is not one of the major killer diseases, but it is usually considered to reduce animal productivity by something like 25 per cent so that it stands high on the list of diseases which the livestock industry would wish to see eliminated.

## Epizootic Areas

In large areas of Asia, Africa and even some regions of South America foot-and-mouth disease continues to spread virtually unchecked and uncontrolled. In such areas the disease is present at a continuously low level with, from time to time, periods of higher incidence. This situation reflects an interplay between the virus with its different variations and variable immunity in the cattle population. A widespread epizootic due to virus of one type is usually followed by a period when that type is of infrequent occurrence in the area concerned and when the incidence of the disease returns to its low level. The lesions observed in these areas, particularly in indigenous stock, may be slight and restricted to a small number of animals in the herd. From time to time, however, with a new wave of the disease (probably due to a type which has not occurred in the area recently), more severe lesions will be seen. In the absence of very recent infection, the antibody levels in general may be very low and may even be difficult to detect, although subsequently on re-infection a secondary response is obtained with rapid development of antibody.

The situation which has been described of an uneasy equilibrium between virus and susceptible species is only maintained so long as no outside factors are brought in. A new type of virus, or new hosts in the form of fresh animals moved into the area, upset the equilibrium and the disease becomes all too apparent. In Africa much attention is being directed to the problem of cloven-footed game animals as reservoir hosts. In the absence of controlled experiments it is difficult to assess the value of antibody studies in game animals as evidence of infection. In the few that have been studied, it has become noticeable that the highest antibody titres have been obtained in buffalo. In some other game animals such as kudu, the initial titre following infection has been quite low. Nevertheless, game animals have been found to be affected early in the course of an epizootic and in many cases the initial isolation of virus has been in a game animal. It is highly probable that the ecology of the disease in wild animals is not unlike that in the associated cattle. Viruses are found which are adapted preferentially to particular

species and it is possible that wild animals may become infected with strains which produce only minimal signs of the disease, while the same strain transferred to cattle may set up acute and severe infection. The discovery of the existence of carrier animals in domestic stock is an additional factor in bringing about the persistence of virus between outbreaks.

In many European countries, in quite extensive areas of South America and very much smaller parts of Africa and Asia, a determined attempt is being made to restrict the spread of foot-and-mouth disease and in the process its incidence is much more carefully observed. In such areas the characteristic picture is of fairly severe infection and, in the absence of vaccination, extensive spread through the affected herd. In these areas of better agricultural development, control measures restricting the movement of animals and animal products reduce spread and outbreaks can be restricted in this way. In vaccinated populations, severe epizootic spread is usually associated with the appearance of a new type or sub-type, and the same was true of Europe in the first 50 years of this century when recurrent waves of infection occurred at approximately 10-year intervals, with some subsidiary peaks between.

It is in such areas that the incidence of the disease poses a very real problem because the lesions are severe and the secondary complications which result are very damaging to the productivity of the livestock. The most energetic steps are being taken in such areas to reduce the significance of the disease.

"Fringe" areas can be defined as those in which the disease is eliminated for relatively long periods up to a year or even up to 5, 10 or 20 years. In general in such areas the control of the disease has been by eradication by slaughter, and the careful observation of animals after an outbreak has been controlled makes it highly unlikely that new outbreaks are derived from virus circulating in the population. New outbreaks occur rather from importation of the disease from enzootic areas and therefore geographical links with infected areas are not always necessary. The Scandinavian countries, the United Kingdom, the United States and Central America are in this category, although the actual number of outbreaks observed varies from country to country. In all these areas, unless vigorous control measures are applied, the virus spreads rapidly in the susceptible population and the outstanding feature is the ease with which chance contacts lead to secondary outbreaks.

## Free Areas

Some of the areas which are "free" from foot-and-mouth disease have achieved this position as the result of geographical isolation and maintained it by the application

of quarantine measures or restrictions on imports. Among such areas are Japan, Australia, New Zealand and North America. There are also areas, such as the southern part of Argentina, which although on the edge of areas affected by the disease do not themselves appear to become affected.

Although antigenic variation is not the only kind of variability encountered in foot-and-mouth disease virus, it is the one which is most spectacular and which is most frequently discussed. The situation in relation to antigenic variation becomes more complex year by year. At least forty distinct antigenic strains of the virus of foot-and-mouth disease are now known and there is no reason to believe that this list is exhaustive. The degree of antigenic difference between strains varies. The more extreme differences have allowed identification of the seven major type groups, which are known as the immunological types. Lesser differences within these groups are classified as sub-type differences. The seven major types and the dates of their identification are as follows:

- |                 |                               |
|-----------------|-------------------------------|
| (1) Type O      | Vallée and Carré (1922)       |
| (2) Type A      |                               |
| (3) Type C      |                               |
| (4) Type SAT 1  | Waldmann and Trautwein (1926) |
| (5) Type SAT 2  |                               |
| (6) Type SAT 3  |                               |
| (7) Type Asia 1 | Galloway <i>et al.</i> (1948) |
|                 | Brooksby and Rogers (1957)    |

The degree of difference between these types is such that an animal recovered from an infection with one remains susceptible to the others, although there is satisfactory immunity against re-infection with strains of the same type. Recently a number of strains have been found which although belonging to the same general immunological group do not confer the solid immunity indicated by such cross-immunity tests, and a proportion of animals will fail to become immune to challenge with some other strain within the same type group. There will, however, be no immunity to strains of other types.

In endemic areas the importance of types lies in the fact that successive waves of infection may pass through the area at relatively short intervals without the necessity for a time interval for the waning of immunity against the homologous virus. We have encountered three types within a few months in certain areas of Africa and we even have records of animals which have passed through infection with three different types of virus under natural conditions within six months. In the more highly developed areas where vaccination is practised, the type situation greatly complicates the planning and execution of vaccination campaigns.

Infection by sub-type strains within a type generally produces a satisfactory immunity to other sub-type strains of the same type. The range of difference between sub-types, however, is now varying from that which is not readily detectable unless fairly precise methods are applied, to a difference which approaches that in which the immunity of the recovered animals is broken down. In the field, sub-types are generally recognized first when vaccination fails to give the expected result.

### High Lability

Observations have recently been made on the possibility of change of sub-type in experimental conditions. Hyslop has shown that passage of the virus in immune animals or partially immune animals leads to the development of a new sub-type different possibly from any which have hitherto been recovered in the field. Parallel experiments have been carried out on the passage of virus in culture in the presence of serum and this also leads to the development of new sub-types. A third method for producing sub-type change is recombination of two virus strains grown in tissue culture. The demonstration of changes produced in this way in the laboratory shows how readily new sub-types might arise in the field and,

because the mutation rate of some strains of virus is of the order of  $10^4$ , many new strains must undoubtedly arise. Whether all of these reach the proportions of producing new outbreaks in animals is problematical, but it would seem more likely that only when conditions are highly favourable or the new strain is very widely different from strains which have been present before does preferential infection with the new strain as opposed to the one previously prevalent take place. Once a strain has broken through, it may persist through many serial transfers in animals. This is particularly true if it is widely different from the earlier strain.

Besides the variability of the virus in the antigenic sense, other changes in virus may be important in epidemiology. The most obvious of these is the change in virulence. It is commonplace that not all outbreaks of foot-and-mouth disease appear to attack the animals with equal severity and there seems little doubt that a change in virulence does occur. Many strains of virus from a major epizootic in Mexico were examined at Pirbright in the 1940s and these strains were shown to be of poor spreading power and of low virulence in the animals affected.

### High Endurance

An outstanding characteristic of the virus of foot-and-mouth disease is its capability of survival outside the body. Much of the early research work on the virus from the mid-1920s to the mid-1930s was devoted to the definition of the periods for which virus could survive under conditions simulating those to be found in the field and tests on virus dried by no particularly refined method on surfaces such as hay, straw, wood, etc., gave results in which the virus survived for periods of fifteen weeks or sometimes more. In the field there is a great deal of evidence of the survival of virus for long periods under natural conditions. On many occasions vehicles which have been used for the transport of animals in the early infective stage of the disease have, without proper disinfection, been used for conveying other groups of animals and frequently it has been found that the virus has survived for several days between two batches of animals being transferred by the same vehicle.

Some factors do militate against survival. Exposure of the virus to direct sunlight decreases survival time, so does a higher temperature. The spread of the disease in warm, sunny, dry climates does not appear to take place so easily by indirect methods as in colder, damp and dull climates. Unfortunately, however, we cannot rely on meteorological circumstances for prevention of spread, because even under adverse conditions the virus of foot-and-mouth disease appears to be very considerably tougher than most other micro-organisms.

Another aspect of virus survival which is important in epidemiology in regard to spread between countries is the survival of virus in meat and animal products which have been derived from infected animals. While the muscular tissue in slaughtered carcasses becomes acid during rigor mortis and so inactivates the virus which may be present, this is not true of certain offals such as liver, kidney and tripe or of the lymph nodes and bone marrow. Prolonged survival has been demonstrated in such tissues in animals slaughtered during infection, and it also seems likely that animals slaughtered in the incubative stages may be an unsuspected source of dissemination of the virus. There has been strong circumstantial evidence that meat from South America has been responsible for a fairly high percentage of the outbreaks in Great Britain, and improvement in control measures in South America, together with restriction on certain classes of animal products coming to Britain, is one of the factors which have contributed to the decrease in the amount of infection in Britain.

Although the virus of foot-and-mouth disease infects the cloven-footed domesticated and wild animals, differences in severity of the disease in various species are often

observed. Some strains of virus will infect pigs but not cattle and strains have also been found which infect cattle but not pigs. There are intermediate strains which affect both species equally readily. Under laboratory conditions it has not proved possible in a small number of passages to modify the virulence of one of those strains so that, for example, a strain normally virulent in pigs and not in cattle becomes virulent for both species. The number of attempts has been small, however, and there is little doubt that such a change must take place in the field and indeed there has been evidence of an increase in the number of cattle outbreaks in Holland. These findings suggest that species adaptation may have an epidemiological significance in that one species may act as a reservoir of infection for the other.

A similar relationship has been observed in the case of strains of virus which have shown a variable degree of virulence for sheep. The strain of SAT 1 which spread through the Middle East in 1961 undoubtedly produced a more severe disease in sheep than many other strains of virus, although at the same time it was capable of producing severe lesions in cattle. In general, however, the A<sub>22</sub> going through the same area has not been notably severe in sheep. Henderson and McLaughlan showed that the European hedgehog could be an important factor in the transmission of the disease from an initial focus of infection to a number of secondary cases in Norfolk. Recently, Capel-Edwards has drawn attention to the susceptibility of the coypu. Man appears to be marginally susceptible, but there are no records of transmission chains from cattle to man and back to cattle, nor, fortunately, strains which are preferentially adapted to man.

### Declining Immunity

An essential part of the epidemiology of a disease is the immune response of the affected animal. The immunity of an animal recovered from foot-and-mouth disease is generally conceded as lasting for 2-4 years or even longer against a homologous strain of virus, if this virus is presented to the animal by way of contact infection. There are certainly no records in the field of re-infection of animals with a strain of virus known to be identical with that from which the animal originally recovered. It must be realized, however, that, although the animal is immune for contact infection, its immune status is not constant throughout this period of recovery but is declining at a rate which seems to vary with the strain of virus involved in the original infection and with other unknown factors during the period of recovery. In general, duration of antibody persistence is correlated with the initial titre which is achieved. This may depend on the condition of the animals, their nutritional status, their age, and may even depend on the breed involved. The picture is one of a gradually declining immunity which leaves the animal progressively more susceptible to re-infection. Opposing this declining immunity is the virus which, by changing as described earlier, may be increasingly capable of infecting the animal in the face of the antibody which is circulating. Obviously, the extreme case is infection with a different type of virus altogether, which may take place within a few weeks even of the initial infection. A new sub-type may be resisted for several months but certainly will not be resisted for as long as the homologous virus. It is rare, however, for the situation to be as uncomplicated as this. In almost any endemic area animals will have been exposed to a variety of antigenic stimuli by different types or sub-types of virus, and the viruses circulating in the area will almost certainly be a mixture, if not of different types, at least of different sub-types which may preferentially infect particular animals. Under such conditions, how many minor infections which never become of serious importance do occur is a matter for conjecture. It is only when a sufficiently different type or sub-type appears in the region that a major epizootic does occur.

It is thought that, following infection with the virus, there is continuous multiplication for a period (depending on the strain of virus) of up to 15-18 months. This multiplication is at a low level and research has not yet demonstrated the transference of the virus from the carrier animal to a susceptible animal brought into contact. The epidemiological evidence in various parts of the world suggests that occasionally carrier animals may act as donors to recipient stock. A particularly important point is that modification of virus in respect of its antigenic constitution is possible while the virus remains in the animal. This would favour the selection of new variant or sub-type strains from time to time and, with waning immunity in the surrounding population, the initiation of a new epidemic.

The classical foot-and-mouth disease vaccine has always been an inactivated vaccine, although living vaccines have been applied on a scale that is rather more than experimental. Inactivated vaccines have given good results in areas where they have been intelligently applied and where prompt action has been taken on the incorporation of new sub-type strains as required. The figures for outbreaks in Europe over the past 15 years are sufficient tribute to the general efficacy of vaccination. Those for France and Holland are perhaps the most encouraging. In Argentina the determined campaign which has been waged for the past 4 years now covers almost all the infected areas of the country and, because an important part of the programme has been the improvement of vaccines by quality control, there are signs of a reduced incidence of the disease.

It must be emphasized that properly organized vaccination campaigns covering reasonably large areas are the only way in which control by vaccination will have a lasting effect. The sporadic use of vaccine in countries to protect particular herds during major epizootics is probably scarcely worthwhile because one dose of vaccine is unlikely to give a solid protection, especially if there is some difference between the vaccinating strain and the field strain. Vaccines have also been applied in the creation of barrier zones to prevent the spread of the disease into clean areas.

What then are the prospects for the control of foot-and-mouth disease by vaccination? Given the correct economic climate, the answer is encouraging. Where vaccination campaigns have been vigorously pursued, with due attention to the control of quality of the vaccine, the results have been good even allowing for the existence of a number of outstanding problems such as the difficulty of vaccination of pigs. In Europe and parts of South America we can look forward to the reduction of incidence to a level where affected animals are slaughtered and eradication is within the bounds of possibility.

In other regions, those bordering on the great endemic areas, the problem will be tackled piecemeal. With the vaccines at present available it is important to consolidate a campaign in a limited area and to avoid the temptation to make too great inroads into the unknown. Operations such as the maintenance of the barrier zones suggest that a start may be made on fringe areas, with extension in due course to the endemic area behind the barrier.

Research can help by leading to the production of more efficient and cheaper vaccines with improved keeping qualities under adverse conditions. It may also improve the prospects for living modified strain vaccines which would seem pre-eminently suitable for some operations in endemic areas. Developments in this field have not been so rapid or so successful as many of us had hoped. Where we are faced with the problem of long term protection for cattle in the more under-developed areas where game animals act as reservoirs of infection, it seems probable that modified strains may provide an answer.

On the world basis, the further that the frontier of disease control can be pushed into the endemic areas, the more secure is the position of those countries which have remained free or brought the disease under control.

# Water Balance in a Small Catchment

by

R. C. WARD

Department of Geography,  
University of Hull

The International Hydrological Decade (1965–75) has stimulated hydrological research of many kinds. One project is concerned with a small catchment area in Yorkshire

ALMOST a decade ago the International Geophysical Year was hailed with a blaze of publicity around the world and the letters IGY still evoke in Britain memories of stirring feats and considerable scientific accomplishment, particularly in Antarctica. In 1965 another world exercise in scientific co-operation, the International Hydrological Decade or IHD, began comparatively quietly, perhaps because of its less concentrated time span, so that even now, twenty months after its initiation, little is known about it except by the specialists directly concerned.

## Aims of the IHD

The background against which the concept of the IHD emerged is that of a world "shortage" of water. Quite obviously this shortage is not reflected in absolute terms, because the total amount of precipitation in the world far exceeds the total use of water; in Britain only 11 per cent of the precipitation is used as water supply. But the shortage is reflected in the non-availability of water in certain areas, perhaps because of inferior quality, the cost of exploitation or the physical maldistribution of water from one area to another. In each case there is an increasing need to locate and measure water resources. It is even more important that because the science of hydrology is still in a comparatively early stage of its development there remain large gaps in knowledge of the theory and fundamentals of the occurrence, distribution and movement of water over, under and through the surface of the Earth.

The activities of the Hydrological Decade are concentrated on these two principal aspects of the problem. According to a statement of the aims, "the programme will focus on science but will give strong consideration to utilitarian factors"<sup>1</sup>. Whereas in the case of the IGY, however, most of the principal objectives were achieved by means of intensive observations over a short period, the very nature of hydrological phenomena, and particularly the variability of hydrological regimes, means that a much longer study period is necessary. It is for this reason that a 10 year programme has been adopted.

In detail, the scientific objectives of the IHD are far reaching in their scope and implications. They include, first, an appraisal of the state of knowledge of world hydrology; second, the standardization of methods of data collection, compilation and reporting; third, the establishment of basic hydrometric networks and the improvement of existing networks in order to provide data about a wide range of hydrological systems varying in size from small catchments to the world as a whole; and fourth, research on particular hydrological systems, known as "representative basins", in selected geographical, geological and climatic environments. It is also intended that there should be research on specific hydro-

logical problems the nature and importance of which demand an international rather than a local effort. theoretical and practical training in hydrology and ancillary subjects, and the systematic exchange of information.

The principal objectives can thus be summarized as the collection of basic data, systematic research and the investigation of water balances of specific areas. Of these, I am concerned particularly with the third. In order to furnish the information that will be necessary if the objectives are to be attained, data are being collected from different types of recording stations and experimental areas. Most of the basic data are being provided by networks of observation stations concerned largely with precipitation, streamflow, evaporation and, in some cases, groundwater. At present, observation stations are standardized only for certain types of measurement; however, it is proposed that standardization will eventually be extended to cover all types of observation in order to reduce problems of data interpretation, and also that the density of existing hydrometric networks will be increased.

A further attempt to improve the international comparability and reliability of data involves the establishment of "decade stations" at which a high standard of accuracy, uniformity and continuity of data collection is maintained, so that the results may be confidently used by all hydrologists. In countries which are already well equipped, this has simply involved specifying certain observation stations as decade stations, but elsewhere the decade stations have had to be specially built in order to create an international network that is sufficiently dense and representative<sup>2</sup>.

The basic units for water balance investigations are the representative and experimental basins. Although sizes will obviously depend largely on natural conditions, the "representative basins" are usually the larger areas—although they rarely exceed 1,000 sq. km. They have been selected, so far as possible, in areas where the hydrological cycle has not been greatly disturbed by man. Nevertheless there will be no attempt deliberately to prevent human activities liable to have hydrological repercussions. Although, in some cases, little more may be involved than the installation of simple instrument networks for precipitation, stream flow and, where possible, groundwater level observations, most representative basins contain at least one decade station. The smaller "experimental basins" are those in which natural conditions, and particularly the vegetation cover, will be deliberately modified and an attempt made to determine the effects of this modification on the hydrological cycle.

Finally, there is a need for data from "benchmark basins" which are still in their natural state and the hydrological regimes of which are completely unchanged

by man. These data will indicate long term natural trends and will serve as a reference base against which data from experimental and representative basins can subsequently be compared.

### Water Balance Research in Great Britain

In Great Britain, water balance research along the lines suggested was given a considerable initial impetus by the Water Resources Act of 1963, which laid statutory obligations on the newly created River Authorities to survey the water resources of their areas and, in particular, to establish hydrometric schemes for measuring rainfall, evaporation and water flow, and to assess underground resources<sup>3</sup>. With the advent of the IHD, there was a rapid increase of research activity so that now, for the first time, widespread systematic and local regional water balance studies are being conducted simultaneously in many parts of the country. Many experimental catchment studies are being or have been established by river authorities, by university departments and by the larger research institutions such as the Road Research Laboratory, the Hydrological Research Unit of the Hydraulics Research Station, and the Water Research Association. An experiment designed by the Department of Geography at the University of Hull is typical of work being planned elsewhere, and will illustrate the scope and scale of the problems involved and will emphasize the need for the rapid collation and integration of results from individual experiments, not only in Great Britain but also on a world scale.

### The Holderness Catchment

The catchment selected for a 15 year programme of investigation covers an area of approximately six square miles in the plain of Holderness and is located some ten miles east of Beverley (Fig. 1). Holderness is a boulder clay plain the surface of which rises very gently towards the coast so that the drainage of most of the area flows into the Hull Valley or into the Humber. The land surface consists principally of hummocky moraines and ridges and shallow enclosed basins such as the one containing Hornsea Mere. Only at one point is a height of 100 ft. O.D. attained<sup>4</sup>. In the experimental catchment itself, the highest ground is about 80 ft. O.D. and the total amplitude of relief is approximately 55 ft., so that

most of the slopes are quite gentle. Soil types are varied, ranging from the light easily worked soils on the higher gravel areas to fairly sticky clay loams in the bottom of the depressions. Most of the area is under mixed farming with a rotation of grass and corn crops. The acreage of woodland is extremely low.

Average annual rainfall over Holderness ranges from about 24 inches in the south to approximately 26 inches in the north and is evenly distributed throughout the year with no one month receiving more than 10 per cent of the average annual total<sup>5</sup>. Intense storms are not characteristic of the area and those which have been recorded have occurred in the summer months between May and August<sup>5</sup>.

On the basis of all these considerations, and assuming an average annual evapo-transpiration total of 20 inches, it was calculated that the probable normal maximum discharge of the selected catchment area would not exceed 50 cusecs. There has previously been no continuous gauging of clay streams in this vicinity, although the upper reaches of the River Hull draining largely from the chalk of the Wolds have been gauged regularly or continuously at three stations. In the planning of this experiment there was thus little evidence to confirm the value of 50 cusecs, although some indication of its validity was provided by the fact that between 1953 and 1962 the daily maximum discharge of the West Beck, the larger of the two main headwater streams of the River Hull, ranged from 4.7 cusecs per sq. mile to 1.6 cusecs per sq. mile. Allowance was, of course, made for the fact that most of the 74 square miles of the West Beck catchment are located on chalk and that both daily totals and instantaneous values are, therefore, likely to be significantly lower than from an impervious clay catchment. In fact, during the very wet period since the beginning of the study in October 1965, the design flow from the experimental catchment has been briefly exceeded on a number of occasions.

A wide range of instruments has been installed with the view, initially, of quantifying the components of the general water balance equation

$$\text{water income} = \text{water losses} \pm \text{changes of water storage.}$$

Assuming that the catchment is geologically watertight, all water income is in the form of precipitation which must, therefore, be measured very carefully. As well as the existing network of standard 5 inch rain gauges, records from which are received by the Meteorological Office, and a number of Dines tilting siphon autographic rainfall recorders maintained by various authorities, two further Dines tilting siphon recorders together with 5 inch check gauges have been installed, one at each end of the experimental catchment. These autographic recorders have been fitted with the strip chart mechanism recently developed by the Meteorological Office and which makes it possible for the gauges to be left for up to four days before the chart must be renewed. This is important in a long term project, when daily attention to the more distant instruments may not be possible. Information is thus available from which the total amount, duration and intensity of rainfall on the catchment area may be readily computed.

The loss of water from the catchment area occurs in several ways, each of which must be accurately assessed. Streamflow from the entire catchment is measured by means of a trapezoidal flume in conjunction with a rotary type of autographic water level recorder. The flume is constructed in rot-proof timber and marine plywood to a design only slightly modified from that first used by the Water Research Association in 1962 (ref. 6). Subsidiary flow measurements are made as required, particularly during very high or low flows, using current meters at selected, stable stream or drain sections.

Apart from the removal of water by means of streamflow, evapo-transpiration constitutes the principal water loss and is also one of the most difficult parameters to

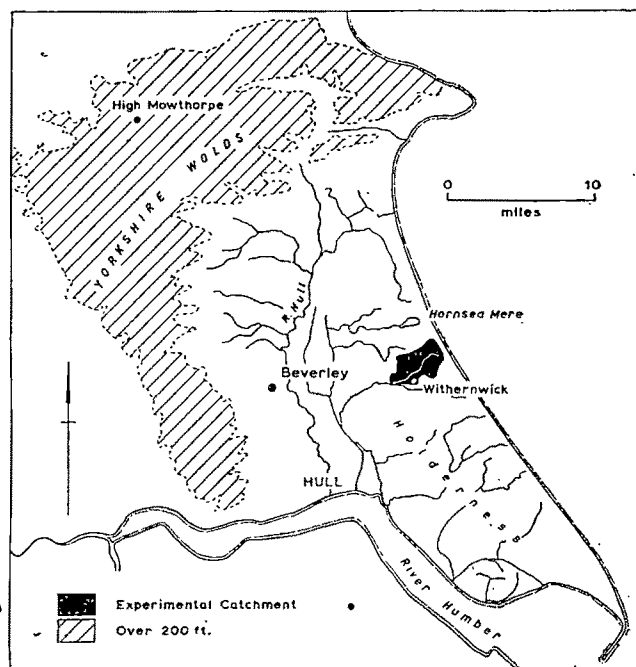

Fig. 1.

determine with precision. In the present study various techniques are used. Thus potential evapo-transpiration, which occurs when soil moisture supplies are at all times adequate for plant needs, is measured by means of an evapo-transpirometer with three grass covered soil tanks<sup>7</sup>. The amount of daily drainage from the base of each tank is subtracted from the amount of rainfall and irrigation on its surface, leaving a value which, when adjusted for changes of soil moisture storage, represents the amount of water used by evapo-transpiration. Open water evaporation is measured in a British Standard sunken pan (6 feet square and 2 feet deep) and also in a United States Weather Bureau Class A pan (4 feet in diameter and 10 inches deep) mounted on a timber framework. The relative merits of these instruments have previously been discussed at some length<sup>7,8</sup>. At this point it is sufficient that each is likely to give a different value of water loss as a result of variations in evaporating surface and exposure. In theory, the evapo-transpirometer should provide the most useful measurement of potential catchment water losses, provided that it is properly exposed and adequately maintained, although there are recent indications that equally valid results can be obtained more readily by using the British Standard pan. The Class A pan inevitably gives an exaggerated value of evaporation because of its exposure, although this can be readily corrected by applying a reduction factor or pan coefficient. This pan has been included in the present study in order to facilitate correlations with results from the many areas of the world in which it is widely used.

Measurements are also made of the meteorological data required to estimate potential evapo-transpiration. Mean daily temperature and humidity are derived from standard and recording maximum and minimum and wet and dry bulb thermometers and the run of the wind from a cup type of anemometer situated at a height of 2 metres above the ground surface. The Penman evapo-transpiration formula also requires the measurement or estimation of net radiation at the vegetation surface and for this purpose a net radiometer has been installed (C.S.I.R.O.). Because of the delicacy of this instrument, however, and particularly because of its susceptibility to damage by birds, net radiation measurements are supplemented by observations of the duration of bright sunshine. An estimate of net radiation can then be made, provided that a direct correlation between this parameter and the duration of bright sunshine has previously been established in the local area. Some measure of the soil heat flux, which is needed for a correct evaluation of evapo-transpiration losses, is obtained from continuously recording earth thermometers at depths of 1 and 4 feet.

Finally, a measurement of the actual evapo-transpiration loss occurring under the prevailing soil moisture conditions will be possible with the proposed installation of a simple weighing lysimeter similar to that being developed at the National Vegetable Research Station at Wellesbourne<sup>9</sup>.

Changes of water storage throughout the catchment are reflected in variations of soil moisture content and groundwater levels and in general the importance of these varies inversely with the time interval. Soil moisture content, like evapo-transpiration, is difficult to measure with precision even with instruments such as neutron probes<sup>10,11</sup>. Many of the common methods of measurement (tensiometers, porous blocks and so on) are either valid only over a narrow range of moisture content or are of doubtful accuracy. In the Holderness experiment, soil moisture variations are determined by weighing and drying samples taken in the field, although it is hoped that a neutron probe will eventually become available. Groundwater levels are measured regularly in existing wells and these data will shortly be supplemented by information from continuous water level recorders in a number of wells and boreholes in the catchment area.

The data collected from these instruments are not sufficient either for a proper evaluation of the general water balance of the catchment area or for more detailed studies of the interactions and relationships between selected parameters. Thus, for example, understanding the interaction between rainfall and run-off also requires detailed information about time and space variations of infiltration capacity, areal variations of crop and vegetation cover and steepness of slopes.

## Conclusions

This brief account of the use of specially designed catchment experiments and their instrumentation will have indicated that although the scale of such studies may be small—merely 6 square miles in this experiment—the physical problems of collecting the necessary data are considerable. But the problems of data processing and analysis are even more taxing. Computers must be used in order to reduce the work to manageable proportions. There are further problems in relating the results from one catchment study to those from similar experiments elsewhere. Fifteen such experiments in the British Isles alone are in active operation and many more are at the design stage. In the United States more than one hundred and fifty have been set up<sup>12</sup>. Rapid and concise publication of results and preliminary analyses is obviously a pressing need if an unmanageable backlog is to be avoided.

The problems of water resources and allocation of water in the U.S.A. are discussed by J. L. Fisher in *Future Environments of North America* (edit. by Darling, F. F. and Milton, J. P.) (The Natural History Press, New York, 1966). He says: "Undoubtedly, demand for water will increase considerably in the years ahead as it has in past decades. Here again improvements in management of water supply, such as treatment and re-use, can make it possible for fairly large increases in demand for specific purposes to be met without a severe general problem of shortage. In the eastern part of the United States plentiful rainfall fairly evenly distributed indicates that the chief problem will not be one of sheer supply, but rather one of maintaining or improving water quality. In the West the chief problem will probably remain that of assuring sufficient supplies, but even in quite arid places, some shift in use away from irrigation toward municipal and industrial uses would make possible a continued population increase and industrial development. In the West more than 90 per cent of water withdrawn from streams and underground sources, and actually depleted or used up, goes for irrigation of crops many of which are in surplus supply.

"The spread of environmental pollution in many forms is one of the more noticeable and objectionable trends of our times. In addition to water pollution, the atmosphere in many metropolitan areas at certain times is heavily polluted, thereby imposing costs and irritations for large numbers of people. Much has been written recently about what may be called the pollution of agricultural land, lakes and streams, and the ground and foliage, generally as a result of the way in which certain pesticides are used."

## BOOK REVIEWS

### GENETIC APOCALYPSE?

#### Genetics and the Future of Man

Edited by John D. Roslansky. (A Discussion at the Nobel Conference, organized by Gustavus Adolphus College, St. Peter, Minnesota, 1965.) Pp. xii+204. (Amsterdam: North-Holland Publishing Company, 1966.) 18 guilders; 36s.

IN 1963 the Nobel Hall of Science was dedicated at Gustavus Adolphus College, St. Peter, Minnesota, as a memorial to Alfred Nobel. In January 1965 the first Nobel Conference was held there, and among the participants were, we are told, four Nobel laureates. According to the dust cover of this book, the conference was attended by eight thousand people and the lectures delivered are presented in *Genetics and the Future of Man*.

The conference was introduced by Polykarp Kusch, and consisted of six lectures. Of these, two, by Sheldon C. Reed and Bentley Glass, are fairly standard and uncontroversial accounts of the genetical adjustments which human populations might undergo in stable and unstable physical environments. Edward L. Tatum follows with an account of some of the things that might be achieved by techniques being developed for treating human cells like cultures of micro-organisms. William B. Shockley discusses population control and eugenics as it appears to a professor of engineering science and does so in a rather "grass roots" kind of way, in the course of which he falls into one of the classical genetical errors of confusing the apportionment among contributory agencies of the causation of a character itself with the apportionment of causation of the variation it is observed to show. The geneticist may find it difficult not to regard parts of this presentation as bordering on the unsophisticated, but at least Shockley emphasizes the need for "a continuing objective fact finding approach to these enormously controversial, enormously significant problems" even if the problems themselves are neither clearly set out nor clearly agreed by the participants in the symposium—perhaps because the necessary facts are not yet available.

Moral and religious implications are discussed at length by Paul Ramsey, who holds a chair of religion at Princeton. He takes his text largely from Muller and the genetic Apocalypse which he sees Muller as foretelling, and leaves at least one reader with the feeling that his discussion, closely argued as one would expect from a student of religion and ethics, would have had more impact if it had taken the genetic Apocalypse less for granted and had insisted on a firmer assessment of the genetical problem with which our ethics would have to cope. Lastly, Kingsley Davis analyses the sociological aspects of genetic control. He exposes the weakness of many of the arguments for genetic control as based on the assumed genetic consequences of social practice itself rather than on independently ascertained facts. He points to the resistance to any drastic programme of hereditary improvement inherent in the stability system of existing societies, and envisages change as more likely to be precipitated by a genetic crisis, possibly consequent on a nuclear holocaust, but sees some genetic change as essential if man is to overcome the limitation to his socio-cultural evolution—*itself* a novel and by no means obviously valid notion.

This book touches on subjects of vital interest to everyone and it makes interesting reading if only for the contrasts and disparities of assumption that it brings out. One wonders what the eight thousand who attended the

conference made of it—perhaps that before we can discuss fruitfully the problem of controlling the genetic structure of mankind we need to know more certainly what is now happening to that structure and to decide more clearly how far the continuing biological evolution of man (as distinct from the control of hereditary disability) is really as essential to continuing social progress as some of the speakers seem to have taken for granted.

KENNETH MATHER.

### WEATHER

#### Physical Climatology

By William D. Sellers. Pp. viii+272. (Chicago and London: University of Chicago Press, 1965.) \$7.50; 56s.

PROFESSOR SELLERS'S book has the same title as the well known book by H. Landsberg, but the two texts are very different. Professor Sellers concentrates more on physics and less on climatology, and his treatment is rather more advanced than that of Landsberg.

The variety of subject matter covered in the thirteen chapters of this book may be judged from a few chapter titles, such as "The Radiation Balance", "Heat Transfer in Soil", "Atmospheric Diffusion" and "Paleoclimatology and Theories of Climatic Change". To me the most attractive chapters are those which deal with radiation and the water and energy balances.

The basic facts and theories of solar and terrestrial radiation have no doubt been treated adequately in many books, including Brunt's classical *Physical and Dynamical Meteorology*, but Professor Sellers succeeds in stimulating the reader even in his tables and diagrams. For example, one table strikingly compares the energy equivalents of many natural and man-made phenomena; thus it appears that the quantity of solar energy received each day on the Earth is equivalent to the energy released by  $10^4$  hurricanes or by  $10^8$  Nagasaki atomic bombs. Apart from the value of his tables, it is pleasant to see so much up to date information; for example, the data on surface albedo were published by Kung *et al.* as recently as 1964. At the same time, Professor Sellers never fails to quote old authorities whenever their work is still relevant. Appropriately, the well known empirical formulae for effective outgoing radiation from the Earth's surface formulated by Ångström (1916) and Brunt (1932) are discussed with later equations developed by Elsasser and Budyko and others, including two formulae of Swinbank (1963) which have, surprisingly, only surface temperature as the independent variable. Equally appropriately, in a summary of estimates of the annual poleward heat flux at various latitudes of the northern hemisphere required to balance the radiative sources and sinks of energy in the atmosphere and at the surface of the Earth, it is interesting that G. C. Simpson's figures of 1929 are substantially the same as the latest estimates made by Budyko and London.

Professor Sellers clearly demonstrates the connexion between rainfall, evaporation (or evapotranspiration), run-off and the convergence of the flux of moisture through the water balance equations for the Earth's surface and the atmosphere, based on the principle of the conservation of matter. Climatological estimates of the various terms are given for particular geographical regions, for the oceans and the continents and for different seasons; they are of fundamental importance in connexion with the rather local problem of water conservation, in the classification of climates and in the general circulation itself. The author next links together radiation and moisture (or water) in balance equations based on the conservation of energy. The energy balance equations are thoroughly discussed, with the aid of informative graphs, for the Earth's surface, for the atmosphere and for the combined system of Earth and atmosphere.

Professor Sellers's book brings together various loosely connected topics which are not at present available in English. His writing is clear and economical, and the bibliography is up to date. The book is strongly recommended to students, but it should also be very useful to many meteorologists.

R. MURRAY

## HISTORY FOR SCIENTISTS

### Chymia

Annual Studies in the History of Chemistry, Vol. 10. Edited by Henry M. Leicester. Pp. 258. (Philadelphia: University of Pennsylvania Press; London: Oxford University Press, 1965.) 40s. net.

*Chymia*, the tenth in the series of annual publications, contains the following articles: "How Old is Hydrochloric Acid?", by L. Reti; "Christophle Glaser and the *Traité de la Chymie, 1663*", by R. G. Neville; "Berthollet, Proust, and Proportions", by S. C. Kapoor; "Unpublished Letters from H. Sainte-Claire Deville to B. S. Yakobi", by Y. I. Solov'ev; "Induced Oxidation-reduction Processes, the History of a Chemical Paradox", by E. Farber; "A Precursor of the American Chemical Society—Chandler and the Chemical Society of Union College", by E. K. Bacon; "Historical Sketch of the Electron Theory of Organic Chemistry", by G. V. Bykov.

The criteria for judging this book are provided by the publishers in a statement on the dust-cover: "The publication of scientific literature has reached such vast proportions in recent decades that the specialist is hard pressed to keep up with developments even in his own limited field. The history of science is thus largely neglected in favour of current findings and it has become increasingly difficult for the reflective scientist to maintain a sense of development, over centuries, of his area of study. *Chymia* is an attempt to supply, in the field of chemistry, information necessary to this perspective".

With the exception of those by Solov'ev and Bykov (the latter is excellent, and will greatly interest physicists as well as chemists) the articles show no evidence of having been written to provide interesting perspective for reflective scientists. The reason that the hard-pressed specialist neglects the history of science in favour of recent findings is that this book is the sort of material that he is offered by the historians. It is specialist, pedantic history written for a diminishing circle of specialist, pedantic historians. Do the publishers really believe that scientists in search of perspective will pay £2 of their own money for a book consisting mainly of long and obscure accounts of historical niceties adorned with the familiar archaic trappings so beloved by venerable scholars (untranslated passages of Latin, reproductions of the title pages of old books, hundreds on hundreds of footnotes, the main purpose of which seems to be to demonstrate that the authors have access to well-stocked libraries)?

If science historians are genuinely concerned about being neglected they must make an effort to present articles that will stimulate and interest scientists who are not historians. They must interpret the past; they must, as Bykov does so well, relate the past to the present. It is not enough to write in detail about the past and expect non-historians to be interested simply because the events described happened long ago, or to describe rare books and expect interest simply because the books are rare. If, on the other hand, they are oblivious to neglect by non-historians (which I suspect to be the truth) they will continue to ignore their important role as interpreters and will continue to write articles like these for each other to read. This is fine—scholarship for its own sake is a necessary human activity, and an enjoyable one—but if the scholar ignores society, he has no right to complain if society ignores the scholar.

R. G. PARTINGTON

## MEN OF STEEL

### The Sorby Centennial Symposium on the History of Metallurgy

Cleveland, Ohio, October 22–23, 1963. Edited by Cyril Stanley Smith. (Metallurgical Society Conferences, Vol. 27.) Pp. xxii+558. (New York: Gordon and Breach; London and Glasgow: Blackie and Son, Ltd., 1965.) 156s.

In this, thirty-six authors from six countries combine to cover in thirty-three chapters the lives of a number of pioneers of metallurgical science technology and techniques and the history of a variety of metallurgical phenomena, methods and theories mainly relating to iron and steel. The mass, or more correctly the volumes, of technical literature with which scientists and technologists are faced today is physically burdensome and mentally overwhelming since almost by definition most worthwhile books require sustained concentration if their reading is to be effective. The contents of the chapters of this centennial tribute by three American societies, principally to H. C. Sorby and other English metallurgists, can be read in relaxed fashion and the chapters, which are largely unconnected with each other, can be taken up at random.

The chapters divide into four groups of different interests—people, phenomena, techniques, particularly metallography and ferrous based materials. As would be expected of so many authors, the style, approach and readability are variable. If generalization is possible, the chapters about people—those individuals who initiated and brought some metallurgical feature to successful fruition—are composed like curriculum vitae, factually incontrovertible but a dull method of presentation; in support one can cite the chapters on J. F. Stead and J. O. Arnold and even the autobiographical chapters by Z. Jeffries and E. C. Bain.

The chapters I most enjoyed, because of the sense of participation in and the feeling of association with the events they describe, were related to phenomena (or lack of them). Today, scientific literature is written in a formalized impersonal fashion<sup>1</sup>. But "The  $\beta$ -iron Controversy" as reported by M. Cohen and J. M. Harris (and the mysterious "jargonium" of Sorby, pp. 37 and 38), "Dislocations in Plasticity" by E. Orowan, "History of Precipitation Hardening" by H. Y. Hunsicker and H. C. Stumpf and "The Development of the Theory of Alloys" by W. Hume Rothery, all had a personal imprint of their authors' sense of excitement. And where individuals write of their own contributions to metallurgical history, it is interesting to compare the introverted, factual, succinct description of the "Note on the Early Stages of Dislocation Theory" by G. I. Taylor with the extroverted exuberant expansive but still factual account of the Hungarian, E. Orowan. These differences lend a great deal of colour as well as surprise to the book.

The early history of metallography and the advanced level to which the technique was brought by Sorby and others should induce humility in the reader and practitioners of the method.

The descriptions of the development of materials—"Iron Manufacture in Britain in the Decade 1850–60", "History of Silicon-iron", "Soft Magnetic Materials", "Tungsten" and "Powder Metallurgy in Development of Dispersion-hardened Materials"—are interesting in that they show some kind of order in the history of the development of these materials even although to the individuals who lived through these developments the successive improvements were achieved in spite of a confusion of facts and misconceptions. It would be pleasing to be able to say that all future developments in metallurgy will be made without having to go through the same bewilderments that faced the several pioneers in this volume, but if this book teaches anything it is that trial and error—with emphasis on the error—is the likeliest way for future developments.

At 156s. all libraries can afford and should have this book, which should be borrowed for bedside reading. I doubt whether individuals even in an affluent society will spend this sum, but since books are still given as prizes in universities and technical colleges, this is useful volume to be kept in mind.

H. M. FINNISTON

## CHEMICAL TECHNOLOGY

### Encyclopedia of Chemical Technology

By Kirk-Othmer. Vol. 6: Complexing Agents to Dextrose and Starch Syrups. Pp. xiv+932. 338s. Vol. 7: Dialysis to Electron Spin Resonance. Pp. xvi+903. 338s. Second completely revised edition. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, Inc., 1965.)

VOLUMES 6 and 7 of the second edition of Kirk-Othmer need little introduction, except that one can congratulate the editors on their efforts, on their choice of another unique list of subjects, and on maintaining the usual high standard.

In this modern age every technologist must be conversant with and capable of using the techniques dealt with under the headings "Computers", "Data, Interpretation and Correlation", "Dimensional Analysis" and "Economic Evaluation". All these articles are concise and informative; they include mathematical derivations and often give examples of commercial and industrial applications. For example, the article on "Dimensional Analysis" explains how this technique has been used successfully to simplify experimental and correlation work applied to the power characteristics of simple turbines. On the other hand, the article on "Computers" could have paid more attention to illustrations of commercial application as in road building or power station construction.

To satisfy the needs of industrial technologists there are reviews on "Conveying", "Distillation", "Crystallization", "Diffusion", "Electrodialysis", "Electrodeposition" and "Electrolytic Machining Methods". In all of them emphasis is placed on industrial applications and on automated processes. The article on diffusion is especially geared to the atomic age, and deals adequately with the theoretical and practical problems associated with isotope separations. The technique of electrolytic machining sounds very attractive and promises much for the future.

Three types of corrosion are discussed in these volumes—corrosion by electrolytic solution, corrosion by gaseous environment, and corrosion by liquid metals or fused salts. Much of the work in the last category has been stimulated by problems arising from the use of nuclear reactors. Volumes 6 and 7 also deal with a wide range of commercial chemicals and raw materials of which only a few can be mentioned. There is a long informative review under "Dyestuffs", and an interesting account of the fluctuations of the world trade in them. The use of Zeigler catalysts in the synthesis of the stereo-specific polymers is dealt with under "Dienes", and of equal importance is the article on "Elastomers" which includes the A.S.T.M. definition of rubber now accepted as providing a boundary line between rubbers and plastics. The proposed use of the vulcanized EPT terpolymers (ethylene-propylene-dicyclopentadiene) in the tyre industry in 1968 is interesting. These volumes give detailed accounts of some important raw materials, including the processing, packaging, preservation and general handling of them. In the article on "Drying Agents" special attention is given to the theories and uses of molecular sieves. In food chemistry there are useful articles on "Confectionery" and "Eggs". The article on "Contraceptives" provides detailed accounts of the chemistry of the hormones. The article on "Dental Materials" is particularly informative and deals with the structure and chemistry of ceramic and polymeric materials

used as cements, and the porcelains, elastomers, amalgams and metal organic products used in dentistry.

K. FIELD

## QUANTUM STATISTICS

### The Theory of Quantum Liquids

Vol. 1: Normal Fermi Liquids. By David Pines and Philippe Nozières. Pp. xi+355. (New York and Amsterdam: W. A. Benjamin, Inc., 1966.) \$15.

### Quantum Field Theoretical Methods in Statistical Physics

Second edition. By A. A. Abrikosov, L. P. Gor'kov and I. Ye. Dzyaloshinskii. Translated from the Russian by D. E. Brown. English translation edited by D. ter Haar. (International Series of Monographs in Natural Philosophy, Vol. 4.) Pp. xii+365. (London and New York: Pergamon Press, Ltd., 1965.) 70s. net.

THE success of the BCS theory of superconductivity and a growing unrest with a basis of the theory of metals have led to an increased interest, and optimistic hope, in the use of the second quantization formalism for the study of the many body problem. This formalism is a necessary part of quantum field theory, but also provides the most convenient framework for all but the simplest many body problems; yet it has two great drawbacks. First, apart from the simplest problems it becomes very complicated both in the precise way in which physical problems are translated into mathematical problems, and in the sheer algebra involved. Second, it is not at all clear how far we have truly advanced in solving these problems, for both superconductivity and the screening of Coulomb forces are only rigorously understood in certain weak coupling limits. There is no doubt, however, that this language will be the one used in new advances and everyone who wishes to follow the present ideas must learn it.

The book of Pines and Nozières, the first of two, gives an account aimed at the graduate student, the experimentalist of low temperature or solid state physics, and the theorist who is not specialized in the field. It leans heavily on the quasi-particle concept put forward by Landau, and emphasizes physical ideas omitting the full ferocity of the theoretical literature. It is a well written book in which the ideas of many body theory are shown to give a basis for the concepts of solid state physics which, though hallowed by time, are only now in the course of being justified. Many solid state effects are discussed in detail, and at the end of the book a realistic account of the validity of current ideas is given.

The book of Abrikosov, Gor'kov and Dzyaloshinskii is very different. It is a full theoretical treatise. This edition was apparently planned as a first translation, but it was forestalled by an American publisher. With additions and revisions amounting to about one sixth of the original it is now presented as the second edition. This is not a book for experimentalists, but it is well established as a theoretical text in its first edition and is a mine of detailed calculations giving in particular a full account of Soviet work in this field. S. F. EDWARDS

## NUCLEAR SAFETY

### The Safe Transport of Radioactive Materials

Edited by R. Gibson. Pp. xi+290. (London and New York: Pergamon Press, Ltd., 1966.) 80s. net.

THE 1964 revised edition of the I.A.E.A. *Regulations for the Safe Transport of Radioactive Materials* is a considerable advance over the first, 1961, edition especially in the classification of radionuclides, more detailed criteria for fissile materials and detailed objective standards for

packaging design. A record of the technical and other parameters on which the revised regulations were drawn up may assist in their application and will provide useful reference material in any future revision. The book fulfils both roles admirably, more particularly as the majority of persons who contributed to it are themselves experts who assisted the International Atomic Energy Agency in the revision.

Part I of the book deals with the regulations themselves and their technicalities. A good overall perspective of the increasing degree of control required as a function of the potential hazards is given in Chapter 7, which ably describes the security considerations to be given to the movement of a large radioactive source. Chapter 1 is an excellent and detailed step by step guide to the requirements of the regulations. It provides an introduction to the comprehensive technical accounts which are given in respect of the control of external radiation, requirements for fissile materials, standards for packaging design, relaxations for materials of low specific activity and the classification of radionuclides, all of which are written in a very clear and readable manner. The administrative body in the regulations is the Competent Authority, particularly important for international transport. The duties of that authority are well described and in detail in Chapter 2; it would have been useful, however, to summarize the philosophy of the regulations in respect of unilateral and multilateral approvals as a function of the availability, or otherwise, of detailed standards and criteria.

The I.A.E.A. regulations are mandatory only for the I.A.E.A.'s own operations; in all other respects they are recommendations to be used as a basis for national regulations, and to be applied in international transport. Part II provides a very useful section in which an account is given of the extent to which the recommendations have been used. It is encouraging to read how widely they have been adopted.

The provisions of the I.A.E.A. transport regulations reflect consideration of both normal and accident conditions in the transport environment. Part III of the book is a concise review of the accidents and incidents involving radioactive materials. Such discussion leads naturally to questions of insurance and indemnity against third party liability in the transport of radioactive materials. Part IV provides a clear and readable description of how such arrangements have been provided for on a European regional, and a national, basis respectively.

G. J. APPLETON

## PROGRAMMING LANGUAGES

### Formal Language Description Languages for Computer Programming

Edited by T. B. Steel, jun. (Proceedings of the IFIP Working Conference on Formal Language Description Languages.) Pp. 330. (Amsterdam: North-Holland Publishing Company, 1966.) 40 guilders; 80s.

THE conference, the proceedings of which appear in this book, marks a significant stage in the development of automatic programming languages. In the early stages of development interest was solely in the writing of compilers; as Dr. Johnson said in another context, it was not done well, but we were surprised to find it done at all. A major advance was made when it was realized that the syntax of a programming language, that is, the rules defining the sentences which can be written in the language, could be expressed formally, and that compilers could be written to work from this formal syntax, thus systematizing their construction. To define a programming language, however, it is necessary to specify not only the permissible constructions—the syntax—but also the meaning of each construction—the semantics. Hitherto, the semantics of a language have been described in an

informal and often pragmatic way, the ultimate definition being the behaviour of the compiler on a particular machine. Attempts are now being made to establish methods for formally defining the meaning of programming languages, and the conference brought together almost every worker in this field at the time.

The methods proposed for formal definition of semantics fall into two broad classes. The first class comprises those methods which develop a meta-language in which to describe the meaning of the programming language. This involves the definition of a number of fundamental concepts of structures in terms of which the more complicated concepts and structures of a programme can be described. The alternative method is to define an idealized machine, often called an evaluating mechanism, and to define formally the action of the machine in response to a piece of programme. In this way the meaning of a programming language is defined by describing what the idealized machine will do when presented with a programme as an input text. The twenty papers in this volume between them cover many variations of these two broad themes. None of the papers attempts very much in the way of comparing and contrasting the various approaches, but at this stage in the development of the subject it is valuable just to have all the different ideas collected in one volume.

For this reason the book is essential reading for anyone starting work in this field, and it should find a place in the library of all computer scientists interested in programming languages.

D. W. BARRON

## GETTING THE SALT OUT

### Principles of Desalination

Edited by K. S. Spiegler. Pp. xiv+566. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1966.) 168s.

SCIENTIFIC and industrial activity in the field of desalination is increasing rapidly, and this book will make a very useful introduction to the topic for those engineers and scientists who find themselves drawn into this type of work.

Although the book is well balanced as a whole, it seems clear that those authors responsible for the separate chapters must each have been given different terms of reference, for most chapters treat their topics in quite different ways. For anyone approaching the subject for the first time, the existing order of chapters would certainly not be the best. Chapter 9, on the "Preparation of Ultrapure Water", would have been a more suitable first chapter.

The concept of energy contained in the second chapter, on the theory of thermoeconomics by Evans, Crellin and Tribus, is not a concept to which an engineer can easily re-orientate after many years familiarity with energy, entropy and the normal manipulation of mass and heat balances. Examples of the use of this new parameter were given in Tribus's paper to the International Symposium on Water Desalination, where its utility was more in evidence than it is in the book.

Silvers's chapter on distillation is a very good fundamental analysis of the mechanics of distillation in large plants. Almost all desalination plants based on land or on ships are of the distillation type and one might have expected Mr. Spiegler to include a chapter on engineering design of distillation plant; perhaps, even, at the expense of the length of the excellently written chapter on vapour reheat.

Lof gives a very good account of the research work on, and the potential of, solar stills, but I cannot agree with his statement that "solar distillation occupies a favoured position among desalination processes in capacity ranges up to 50,000 or perhaps 100,000 gallons/day".

Not many people would be prepared to buy a solar distillation plant with a capacity of 100,000 gallons for \$1 million when the same sized distillation plant would cost nearer a fifth of this amount.

Should anyone wish to obtain a well based knowledge of the theory and practice of electrodialysis, he would be well advised to read the admirable chapter by Shaffer and Mintz; it covers a very wide range of topics in the electrodialysis field in a clear and concise manner. Apart from some operating data from the large electrodialysis plants in America, and which have only fairly recently been published, this chapter covers most of the available electrodialysis information of interest to the desalination engineer. The same words could be echoed in the case of the chapter on reverse osmosis, though both chapters suffer from one small omission—pictures of actual operating equipment. The chapter on freezing tends to go to the other extreme with its almost exclusive devotion to operating plant description, but it does not discuss the difficulties of designing the more intractable components such as the compressor and the wash column; these are some of the main obstacles to the progress of this method of desalination.

Chapter 10 on scale formation and prevention is a useful brief introduction to the subject, but the serious reader would be advised to extend his reading before applying the information here. The final chapter in the book, entitled "The Cost of Conventional Water Supply", applies only to the United States; it does, however, give desalination engineers in other countries a very good idea of the type of local information with which he should be familiar.

On the whole, I and others in the field of desalination have found the book an extremely interesting and well balanced treatment of the subject, though a chapter on steam cycles for combined electric power and desalination plant and one on ion exchange would have made it more complete. A second volume on the same lines but filling in the gaps would make them both a valuable contribution for all those working in the field.

C. R. BENNETT

## BIOCHEMISTRY, 1966

### Annual Review of Biochemistry

Vol. 35. Edited by Paul D. Boyer. In association with Alton Meister, R. L. Sinsheimer and Esmond E. Snell. Part 1: Pp. viii + 1-456 + 91. Part 2: Pp. iii + 457-908 + 91. (Palo Alto, California: Annual Reviews, Inc., 1966.) \$11.50 the two parts.

SINCE it was first published in 1932, the *Annual Review of Biochemistry* has until now appeared each year in a single volume. But the 1966 edition has undergone binary fission and now appears in two parts, each of approximately 450 pages, containing about a dozen scientific articles. In addition, there is the usual introductory autobiographical essay by an eminent biochemist, the contributor on this occasion being A. C. Chibnall, who writes under the title "The Road to Cambridge". Author and subject indexes, together covering both parts of the volume, are printed in each of the two parts, as also is a list of the contents of the whole volume. In addition, there is a cumulative index of chapter titles and contributing authors which covers Volumes 30-35.

As might be expected, the biochemistry of amino-acids, peptides and proteins occupies much space, but a particularly interesting topic is "Water-insoluble Derivatives of Enzymes, Antigens, and Antibodies" by Israel H. Silman and Ephraim Katchalski, the last article in the volume. The "Biochemistry of Bacterial Cell Walls" by Hans H. Martin also covers a new and rapidly expanding field of study which, from an experimental point of view, can be said to date from 1951, when Salton and Horne

described the first practicable method for isolating cell walls from whole bacteria on a preparative scale. Bacteria use building materials of complex composition, the macromolecular organization of which differs from that of the classical linear homopolymers of plant cell walls, and various names have been suggested for this class of substance. Hans Martin has adopted the name "murein", recently proposed in analogy with the term "protein". Whether this terminology will ultimately be used generally remains to be seen.

The review articles in general maintain their expected high standard, and one can say with certainty that the process of fission has had no discernible effect on the contents of the volume but has made available two parts of a size which is most convenient to handle.

F. G. YOUNG

## ARTHROPOD NEUROCHEMISTRY

### The Neurochemistry of Arthropods

By J. E. Treherne. (Cambridge Monographs in Experimental Biology No. 14.) Pp. viii + 156. (London: Cambridge University Press, 1966.) 30s. net; \$6.

To a considerable extent the limitations of the book are the limitations of knowledge about the neurochemistry of arthropods; its highlights depend on the topics that have so far interested the research workers. There is a concentration of research into the neurochemistry of insects and crustaceans mainly because of the availability of these animals.

The central nervous system (CNS) of the insect has a sheath around it which may limit the transfer of material between it and the haemolymph. Water soluble materials pass from the haemolymph into the CNS easily, however, and Treherne suggests that this may explain the problems of the vertebrate blood-brain barrier. In vertebrates there is a restricted extracellular system while in insects there is a large extracellular volume in the CNS.

Plant eating insects such as *Carausius* have blood with an interesting ionic composition; it is poor in sodium (15 mmoles/kg compared with 156 mmoles/kg for *Periplaneta*) and rich in magnesium (53 mmoles/kg compared with 5.3 mmoles/kg for *Periplaneta*). The nerve cord also has a high concentration of magnesium (22 mmoles/kg compared with 2.9 mmoles/kg for *Periplaneta*). Could  $Mg^{++}$  instead of  $Na^{+}$  be entering the nerve axons during nerve activity?

There is still uncertainty about the nature of the chemical transmitters in the arthropod nerve-nerve and nerve-muscle systems. It is likely that acetylcholine is a central transmitter. One difficulty has been that fairly high concentrations of acetylcholine ( $10^{-3}$  g/ml.) have to be added to the CNS to produce a clear effect but, as Treherne and Smith have shown, this is most probably due to the high concentrations of choline esterase that lie beneath the sheath of the CNS. With regard to peripheral transmitters, the evidence for glutamate as the excitatory transmitter in insects and crustaceans is discussed and the more recent papers are mentioned in an addendum to this volume. There is fairly good evidence that gamma-aminobutyric acid may be the inhibitory transmitter at the nerve-muscle junction.

It would have been useful if there had been a chapter on neurosecretion in arthropods, but this might have made the volume too long. There is a limitation placed on the authors of these monographs with regard to space and it is certainly an advantage to the reader if the material is described concisely and succinctly. The present volume provides the best available general account of the neurochemistry of the arthropods—a subject that will be the basis of our understanding of the control system of arthropod behaviour, insecticides, clock mechanisms, and the like. The book should do much to stimulate work into this somewhat neglected subject.

G. A. KERKUT

## ENZYME INHIBITORS

### Enzyme and Metabolic Inhibitors

By J. Leyden Webb. Vol. 2: Malonate, Analogs, Dehydroacetate, Sulphydryl, O-Iodosobenzoate, Mercurials. Pp. xx+1237. 272s. Vol. 3: Iodoacetate, Maleate, *N*-Ethylmaleimide, Alloxan, Quinones, Arsenicals. Pp. xx+1028. 256s. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1966.)

THE subject of this book is an analysis of action of selected enzyme inhibitors in terms of the physicochemical mechanisms of their effect on isolated enzymes and the metabolic consequences of enzyme inhibition on more integrated cellular functions. The effects on animal, microbial and plant cells are discussed without discrimination between species.

Volume 2 contains four chapters—on malonate, analogues of enzyme reaction components, dehydroacetate and sulphydryl reagents respectively. Volume 3 has seven chapters, on iodoacetate and iodoacetamide, maleate, *N*-ethylmaleimide, alloxan, quinones, arsenicals, and comparison of sulphydryl reagents.

Although the author deserves considerable credit for collecting large amounts of material, it is difficult to avoid directing attention to significant shortcomings. The most general is an apparent weakness of logical structure, leaving the impression of a more or less random collection of information which has not been sorted out authoritatively. It is almost unrealistic to expect authoritative knowledge from a single author in as many diverse fields as are dealt with in this work. It would have been less risky to have left many unsolved problems in the form of accurate descriptions of phenomena without attempts at interpretation. The penalty for the author's encyclopaedic ambitions is an unbalanced presentation of both excellent and unreliable references, some inaccuracies of quotation, and occasionally interjections of unfounded subjective opinions. Perhaps the most creditable aspect of the contents of the two volumes is a tendency to emphasize physicochemical considerations. It is unfortunate, however, that important advances in the field of enzymatic mechanisms, particularly relationships of protein structure to catalytic activity, have been virtually ignored. It is equally disappointing that significant advances in molecular biology which provide interesting examples of mechanisms of action of inhibitors are not to be found in these volumes.

A few examples illustrate these shortcomings and may serve as a warning to the reader. On page 44, Volume 2, we find the remarkable conclusion that the active site of succinic dehydrogenase has a "slit or tubular" structure, a statement which, in the absence of more serious physical information, is no comfort to enzyme or protein chemists. Effects on isolated enzymes and on enzyme systems (for example, electron transfer systems) are sometimes confused (that of the calcium ion, for example, on page 47). It is unfortunate that some well-known biochemical mechanisms appear to be *terra incognita* if one wishes to depend on this text for information (including uncoupling of oxidative phosphorylation, Crabtree and Pasteur effects, pages 115, 119, 127; interpretation of lipid metabolism, page 137; omission of participation of carbamyl phosphate in the urea cycle, page 157, etc.). The chaotic method of presenting diverse subjects ranging from inhibitors of fumarase to vitamin analogues is especially evident in Chapter 2 of Volume 2. There are some misquotations of published papers (for example, on page 334), and also noticeable omissions, faults which introduce uncertainty in the text. Although Chapters 5 and 6 of Volume 3 are more carefully organized, they tend to be repetitious.

These volumes will remain sources of varied information without the assurances of accuracy, reliability and up to date interpretation which one expects from an authoritative handbook.

E. KUN

### Polarography 1964

Edited by Graham J. Hills. (Proceedings of the Third International Congress, Southampton.) Vol. 1: Pp. xvi+1-686+xvii-xxviii. Vol. 2: Pp. xv+687-1164+xvii-xxviii. (London: Macmillan and Co., Ltd., 1966.) 315s. the set.

It is sometimes difficult for those actively engaged in electro-analytical chemistry—and impossible for those not so engaged—to appreciate the wide interest in, and the possibilities of, the technique simply described as polarography. Only by perusal of volumes like these does there come a realization of the tremendous impact that polarography has made and continues to make on electrochemistry.

These volumes are a record of the 1964 International Congress of Polarography organized by the Polarographic Society and held at the University of Southampton. The record consists of eighty-nine papers. Among them are reviews such as that by Kolthoff of the fundamentals of polarography in inert solvents; recent trends in organic polarography by Zuman; recent developments in direct current polarography and recent advances in high-resistance polarography. For the specialist there is a range of papers covering as wide a selection as the polarography of oxidized and reduced forms of diphosphopyridine nucleotide to the kinetics of fast reactions. Fully to appreciate the possibilities, it will be necessary to purchase both volumes, but those who do so will find them worth while.

R. J. MAGER

### The Fundamentals of Mathematical Analysis

Vol. 1. By G. M. Fikhtengol'ts. Translation edited by Ian N. Sneddon. (International Series of Monographs in Pure and Applied Mathematics, Vol. 72.) Pp. xxvi+494. (London and New York: Pergamon Press, Ltd., 1965.) 50s. net.

THIS book was originally published in Russian in 1960 and consists of the usual development of analysis at the university level. It starts with the Dedekind definition of irrationals, and uses the concept of variables in discussing the idea of function. Limits are introduced using infinitesimals (null sequences), and the normal development through continuity, differentiability to the Riemann integral and functions of several variables follows. There are applications of the theory to problems of maxima and minima, length of a curve, indeterminate forms and areas and volumes. It concludes with a historical survey of the early works in differential calculus. The main defect from the student's point of view is that there are no exercises, though there are several worked examples.

R. L. PERRY

### The Fundamentals of Mathematical Analysis

Vol. 2. By G. M. Fikhtengol'ts. Translated by Ann Swinfen. Translation edited by Ian N. Sneddon. (International Series of Monographs in Pure and Applied Mathematics, Vol. 73.) Pp. xxi+518. (London and New York: Pergamon Press, Ltd., 1965.) 55s. net.

IN this volume, G. M. Fikhtengol'ts continues the development of analysis through the usual university syllabus. A discussion on the convergence of series is followed by a considerable section on uniform convergence and the interchange properties associated with it. A continuous, nowhere differentiable function is constructed. The text continues with the theory of implicit functions, multiple integrals and Fourier series and integral. Interspersed with the development of the theory are sections on the historical background. The book concludes with a brief introduction to the further developments of analysis. It is a satisfactory, if somewhat lengthy text, covering a little more than is usually included in a specialist pure mathematical course in analysis, though there is no theory of sets or mention of enumerability. Together the volumes contain more than 1,000 pages.

R. L. PERRY

### Chemical Carcinogenesis and Molecular Biology

By Pascaline Daudel and Raymond Daudel. Pp. 158. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, 1966.) 53s.

IN spite of the recent and, in some respects, more detailed book by Clayson on chemical carcinogenesis, this book will be welcomed by biologists. The title is somewhat optimistic as there is still no good tie-up between the understanding of the chemical structure and biochemistry of carcinogens, and the basic molecular biological phenomena. The twelve chapters cover the field briefly but clearly, each containing a useful list of references. Some of the conclusions are less cautious than ideal; for example, the fact that more skin papillomata appear if the carcinogen is given near midnight, and the fact that mitotic frequency in the skin is lower at midnight than at noon; these two observations do not suggest that carcinogens act primarily on cells which are synthesizing DNA. Generally, a more critical approach to the literature would have been useful.

The translation retains some gallicisms: "sensitivity" instead of "sensitivity", "works" of this kind instead of "experiments"; and it is a pity that in the text the letter "l" and the number "1" are sometimes indistinguishable. This may confuse those not expert in the particular field discussed. There are some spelling mistakes, and minor points which might irritate the experts (for example, sulfanoxyalkanes and nitrosamines are classed together), but this readable little book will be useful for students and biologists interested in the complex field of chemical carcinogenesis.

L. G. LAJTHA

## OBITUARIES

### Lord Brain

LORD BRAIN, who died on December 29, aged 71, was neurologist, philosopher and writer.

Walter Russell Brain was educated at Mill Hill School and at Oxford, where his teachers included Sir Julian Huxley, J. B. S. Haldane and Sir Charles Sherrington. His major hospital appointments, until his retirement in 1960, were at the London Hospital, where he was a general and consulting physician, and at the Maida Vale Hospital for Nervous Diseases. From 1924 he was engaged in research, in addition to his practice as a neurological physician, and he published numerous original papers.

At the London Ophthalmic Hospital (Moorfields) he became interested in the ocular symptoms of thyroid disorders, especially exophthalmos, and he described the syndrome exophthalmic ophthalmoplegia—a condition which involves paralysis of the muscles of the eye. In his later clinical neurological work, Brain was particularly interested in carcinomatous neuropathy—the relation between cancer and degenerative changes in the nervous system. He was involved in surveys of patients with cancer, which have shown that there is a connexion between the incidence of cancer and of neurological disorders such as motor neurone disease (amyotrophic lateral sclerosis). He also investigated disorders of the joints of the neck and of the spinal cord as a cause of neurological symptoms. He was an authority on disorders of speech, about which he wrote one of his books, and on neurological disturbances after damage to the major hemisphere of the brain.

Lord Brain, who was a Quaker, was always interested in philosophy, and particularly in the relation between the brain and the mind in perception. In the Linacre lecture, delivered at Cambridge in May 1965, he described perception, in neurophysiological terms, as a method of conveying information to the brain. He also applied his specialized knowledge to literature, which with philosophy was his main pleasure apart from work, and to the many public offices which he held, particularly after his retire-

ment. He was the president of the Migraine Trust, set up last year to finance a programme of research into this disorder, as well as being chairman of the Standing Committee on Drug Addiction, and a member of, among others, the Royal Commission on Marriage and Divorce and the Law Relating to Mental Illness. He had been president of the Royal College of Physicians and the British Association, and was active in the House of Lords; in the committee stage of the Abortion Bill he moved two amendments which were accepted. One amendment replaced as a ground for abortion the possible birth of a child with no prospect of reasonable enjoyment of life with the possible birth of a child with a serious mental or physical handicap. He remarked that the prospect of reasonable enjoyment of life is not something which a doctor can calculate.

### Professor F. E. Ray

DR. FRANCIS E. RAY, aged 68, research professor in pharmaceutical chemistry at the University of Florida in Gainesville, died on November 25 in Hong Kong while he was on a world tour before going to the ninth International Cancer Congress in Tokyo.

Ray obtained his B.Sc. and D.Sc. with Professor Chattaway from the University of Oxford, when he was a Rhodes scholar, and Professor W. A. Noyes supervised his M.S. thesis at the University of Illinois. Ray was a member of the faculty of the University of Cincinnati for many years, and he and his students were pioneers in the preparation of isotopically labelled organic compounds for cancer research when he was the director of the Laboratory of Radiochemistry. In 1949 Ray was appointed director of the Cancer Research Laboratory at the University of Florida, and in 1960 he assumed his last position.

Ray, early in his career, discovered the sulphonium equilibrium and wrote an authoritative review with G. Rieveschl on the chemistry of the polynuclear hydrocarbon fluorene. This proved to be the starting point for Ray's interest in the carcinogenic derivatives of this hydrocarbon, a field in which he and his students made many important discoveries. Thus, his name is associated with new derivatives of the carcinogen 2-acetylaminofluorene; with the induction of adenocarcinoma of the glandular stomach in rats by means of 2,7-diacetylaminofluorene; with the production of minimal deviation hepatomas with *N*-2-fluorenylphthalamic acid, and with the preparation of pharmaceutical products labelled with chlorine-36 and sulphur-35 for metabolic investigations.

Ray was the author of four text-books on experimental, general and organic chemistry which were at one time adopted by many of the major universities in the United States. He was an active member of many learned societies, among them the American Association for Cancer Research, the American Chemical Society, the Society of Nuclear Medicine, the Society for Experimental Biology and Medicine, Sigma Xi, and he was a fellow of the Ohio, the Florida, and the Iowa Academies of Science. He served on a panel on carcinogenesis of the International Union Against Cancer, and as director of the Florida Division of the American Cancer Society and as a member of its Research Committee. He was a consultant to the Medical Division of the Oak Ridge Institute of Nuclear Studies. Ray was an authority on the chemical causes of cancer and he testified on this subject before a committee of the U.S. House of Representatives.

To his students and associates, Ray was more than a teacher; he had a curiosity to delve into the unknown, to read and follow the literature on a broad basis, and the wisdom to develop concepts and ideas based on and guided by experimental facts. Ray loved music not only as a listener; he played the flute in the Civic Orchestra of Cincinnati and the University Orchestra in Gainesville. He liked poetry and expressed his talent for form as a photographer. He was proud of the tropical plants in his garden in Florida.

JOHN H. WEISBURGER

# Absolute Magnitudes of Quasi-stellar Radio Sources

by

G. C. McVITTIE

R. STABELL

University of Illinois Observatory,  
Urbana, Illinois

Absolute magnitudes of quasi-stellar sources, plotted against the logarithms of their red-shifts, fall between two limits. The interpretation of the diagrams varies according to the type of model universe chosen

A NUMBER of recent investigations<sup>1-5</sup> have dealt with the relation between the red-shift and the optical apparent magnitudes or the observed radio flux densities of quasi-stellar radio sources. The object of the present article is to analyse the absolute magnitude of fifty-four quasi-stellar radio sources for which the red-shift,  $z$ , and visual apparent magnitude,  $m_v$ , are available<sup>6-8</sup>. In order to calculate the absolute magnitude of a luminous source from its observed  $m_v$  and  $z$ , it is of course necessary to know the equivalent of its "distance". If it is assumed that the red-shifts are cosmological in origin, the theory of uniform models of the universe may be used to provide the "distance". In fact<sup>9</sup> the formula for the absolute magnitude in a model universe is

$$M_v + C = m_v - (K_v + A_v) - 5 \log D \quad (1)$$

Here

$$C = 5 \log (cT_0/10) \quad (2)$$

$T_0$  is the reciprocal of the Hubble constant, the distance  $cT_0$  is in parsecs,  $K_v$  is the visual  $K$  correction and  $A_v$  the correction for absorption in our galaxy. The function  $D$  of  $z$  is different in each model of the universe and is calculable as soon as numerical values are assigned to the acceleration parameter  $q_0$  and the density parameter  $\sigma_0$ <sup>10,11</sup>. Hence a given  $m_v$ ,  $z$  and  $C$  does not uniquely define  $M_v$ ; the model also contributes to its value.

## The $q_0 = \sigma_0 = 1$ Model

This model possesses the property that  $D=z$  so that (1) becomes

$$M_v + C = m_v - (K_v + A_v) - 5 \log z \quad (3)$$

Fig. 1 shows the plot of absolute magnitude against  $\log z$  for this model. The left-hand ordinate is graduated in terms of  $M_v + C$  and is therefore applicable for any assumed value of the Hubble constant  $1/T_0$ . The right-hand ordinate shows  $M_v$  itself, calculated for  $1/T_0 = 100$  km/sec/Mpc. The straight line  $m_v = 19^m0$  has also been

included in the figure. The large scatter of the points is similar to that found by other investigators<sup>1-5</sup>, but there is also a general slope of the points nearest to the  $\log z$  axis, downwards from left to right, which has been indicated by the dashed line. The extreme left-hand point (3C 273) has been excluded: this quasi-stellar source is quite exceptionally bright for its red-shift. Clearly the upper boundary of the points, exemplified by the line  $m_v = 19^m0$ , can be explained by the limited ability of telescopes to detect faint objects. As was pointed out by McCrea<sup>6</sup>, the area above this line in Fig. 1 may contain many faint objects. But the lower boundary, indicated by the dashed line, is harder to explain. Sandage (personal communication) and McCrea<sup>6</sup> have suggested that it is caused by a volume effect. It is supposed that there are only a small number of intrinsically bright objects which should make them detectable (statistically) only at large distances, that is, in large volumes. We have therefore used the tables of Refsdal, Stabell and de Lange<sup>12</sup> to examine this volume effect.

Table 1

$z$	0.0-0.7	0.7-1.1	1.1-1.5	1.5-1.9	1.9-2.2
Volume $10^3$ Mpc	8.3	9.5	9.9	8.4	6.6
Number with $M_v + C < 16^m5$	0	0	1	1	1
Number - density	0	0	0.10	0.12	0.15
Number with $M_v + C < 17^m0$	0	1	2	1	4*
Number - density	0	0.11	0.20	0.12	0.61*
Number with $M_v + C < 17^m25$	1	3	3	2*	4*
Number - density	0.12	0.32	0.30	0.24*	0.61*

\* These values are somewhat affected by selection.

Table 1 shows the volumes between the intervals of  $z$  indicated in the first line of the table. The third line contains the number of sources with values of  $M_v + C$  less than  $16^m5$  in the relevant volumes, read off from Fig. 1. The corresponding number-densities are given next. Numbers and number-densities are also tabulated for values of  $M_v + C$  less than  $17^m0$  and  $17^m25$ . From

Fig. 1. Absolute magnitudes  $M_v + C$  (arbitrary scale) or  $M_v$  (scale for  $H = 100$  km/sec/Mpc) plotted against  $\log z$  for model  $q_0 = \sigma_0 = 1$ .

Table 1 the dearth of objects with small red-shifts, indicated in Fig. 1, seems to be significant. Hence the volume effect does not appear to be sufficient to account for the empty region below the dashed line, though it must certainly play a minor part. A corresponding result has been found for the steady-state theory by Sciama and Rees<sup>3</sup>, and also by McCrea<sup>5</sup> in discussions wherein the radio flux densities of the sources were used instead of optical apparent magnitudes.

The lower boundary that appears in Fig. 1 may be accounted for by one or both of two secular effects: (a) secular changes in the number of sources per unit physical volume; (b) secular changes in the intrinsic luminosity of each source. If the number of intrinsically luminous sources per unit volume was larger in the past than it is now, then the diagram should show more bright sources at large than at small  $z$ , because a large value of  $z$  means that a portion of the universe as it was in the remote past is under observation. If the intrinsic luminosity of a source decreases secularly, the diagram should show the same effect, namely, a greater number of intrinsically bright objects at large red-shifts (at an earlier epoch) than at small red-shifts. The general slope of the points in the diagram is therefore, on this view, a counterpart of the conclusions drawn from number-counts of extragalactic radio sources many of which are no doubt quasi-stellar sources. McVittie<sup>13</sup> showed in 1957 that the secular effect (b) could be used to interpret the counts made by Mills and his co-workers. More recently the alternative effect (a) has been applied to the counts made at the Vermilion River Observatory<sup>14</sup>. Longair<sup>4,15</sup> favours the secular effect (b) and uses the Einstein-deSitter model ( $q_0 = \sigma_0 = 0.5$ ) in his interpretation of the Cambridge counts.

### The Effect of the Model

There is another quite different conclusion that may be drawn from the basic formula (2). The same fifty-four quasi-stellar sources may be used with a different function  $D$ , that is with a different model universe. The tables of Refsdal *et al.*<sup>12</sup> can be used to recalculate  $M_v + C$  for a number of models. A measure of the magnitude differences (DELMAG) in the tables is  $5 \log (D/3)$ . Fig. 2 shows the results obtained for Milne's model defined by  $q_0 = \sigma_0 = 0$ . The slope of the points in the diagram has been steepened from left to right. The secular effects (a) and (b) have become more pronounced. The model  $q_0 = 0, \sigma_0 = 3$  yields Fig. 3 in which the slope has to all intents and purposes vanished. Secular effects are not required in this case. Finally Fig. 4 is obtained for the  $q_0 = -2, \sigma_0 = 1$  model. Here the slope of the lower boundary has been reversed. This is due to an effect investigated by Sandage<sup>16</sup> and by McVittie<sup>17</sup> by which, in some models, the apparent brightness of a source of given intrinsic luminosity, after decreasing in the usual way up to a limiting value of  $z$ , begins to rise again as  $z$  increases beyond the limiting value.

It is thus seen that the interpretation of diagrams such as those found in Figs. 1 to 4, or of similar diagrams in which apparent magnitudes or observed flux densities are used, must be carried out with great care. All methods employ  $\log z$  as one co-ordinate and it is only in the  $q_0 = \sigma_0 = 1$  model that  $z$  is proportional to luminosity distance. Interpretations that rely solely on this model, or on the Einstein-deSitter or on any other specific model, are likely to be model dependent and thus do not necessarily yield conclusions valid in all possible models.

Fig. 2. Absolute magnitudes  $M_v + C$  (arbitrary scale) or  $M_v$  (scale for  $H = 100$  km/sec/Mpc) plotted against  $\log z$  for model  $q_0 = \sigma_0 = 0$ .

Fig. 3. Absolute magnitudes  $M_v + C$  (arbitrary scale) or  $M_v$  (scale for  $H = 100$  km/sec/Mpc) plotted against  $\log z$  for model  $q_0 = 0, \sigma_0 = 3$ .

Fig. 4. Absolute magnitudes  $M_v + C$  (arbitrary scale) or  $M_v$  (scale for  $H = 100$  km/s/Mpc) plotted against  $\log z$  for model  $q_0 = -2$ ,  $\sigma_0 = 1$ .

Caution suggests that a variety of models should be investigated before final conclusions are drawn. In the present instance, secular effects have been invoked to account for the diagrams of  $M_v$  against  $\log z$ , when the model universe to which the observed universe conforms is of the type exemplified by the  $q_0 = \sigma_0 = 1$  or the  $q_0 = \sigma_0 = 0$  models. But such secular effects would be unnecessary if the model turned out to be similar to the  $q_0 = 0$ ,  $\sigma_0 = 3$  model of Fig. 3.

#### Local Theory of Quasi-stellar Sources

Fig. 2 also throws some light on the local theory of quasi-stellar sources. Suppose that the sources are assumed to have been ejected simultaneously from some point at, or near, our galaxy and that they have subsequently moved at high speeds in the space-time of special relativity. Then those with highest speeds (large  $z$ ) are more remote today than those with smaller speeds (small  $z$ ). Milne's model—which is that of special relativity—therefore applies and Fig. 2 may be used. But since  $C$  is now unknown, the values of  $M_v$  given on the right-hand ordinate are inapplicable. Nevertheless, a large value of  $M_v + C$  still implies an intrinsically fainter object than does a small value of  $M_v + C$ . The presence of the lower boundary (dashed line) for the points in Fig. 2 would imply the existence of a correlation between

speed of ejection and intrinsic luminosity of the ejected object. The physical cause of an explosion which had this property is not apparent. As always, 3C 273 appears as an anomalous object: it is moving too slowly for its intrinsic luminosity. If the quasi-stellar sources are supposed to have been ejected from the explosion centre at different times in the past, or from a number of comparatively nearby centres, however, no conclusions can be drawn from Fig. 2 because then the distances of the sources would be quite arbitrary.

## Determination of Longitudinal and Transverse Optical Constants of Absorbing Uniaxial Crystals—Optical Anisotropy of Graphite

by  
SABRI ERGUN

Bureau of Mines, U.S. Department of the Interior,  
Pittsburgh, Pennsylvania

Equations relating the minimum values of the refractive and attenuation indices to the longitudinal and transverse optical constants are developed. The longitudinal optical constants of graphite are thus obtained

A UNIAXIAL crystal may be regarded as a stratified medium, that is one whose properties are constant throughout each plane perpendicular to the optic axis. To define the medium optically we need to know the dielectric constants along the optic axis and perpendicular to it. To be in harmony with the definition of transverse electric and transverse magnetic waves adopted by Born and Wolf<sup>1</sup>, we shall define the optical properties of the graphite as transverse when the electric vector is per-

pendicular to the optic axis and as longitudinal when the electric vector is parallel to the optic axis. Many uniaxial crystals exhibit natural surfaces perpendicular to the optic axis; hence, measurement of reflectance at normal incidence to such surfaces leads to the determination of the transverse optical properties.

The simplest experiments to obtain the longitudinal optical constants would involve reflexions at normal incidence from the ( $h k 0$ ) faces; one of the extreme values

of the reflectance, the minimum in the case of graphite, is a function of the optical parameters along the optic axis only. Unfortunately such faces suitable for optical measurements are not often available, as in the case of graphite. It therefore becomes necessary to resort to experiments involving oblique incidence of polarized light at the basal planes or to employ crystal faces inclined to the basal planes if normally incident polarized light is used. Although such experiments have been carried out with graphite, the optical constants of this material along the optic axis have not been determined. McCartney and Ergun<sup>2</sup> measured the reflectance at normal incidence in differing immersion media from the 10 $\bar{1}$ 2 face (the so-called *o*-face) of graphite and reported the minimum and maximum values of the refractive and absorption indices at 5461 Å. To calculate the optical constants along the optic axis they made use of the uniaxial indicatrix largely because rigorous equations had not been developed for the analysis of the directional optical properties. The indicatrix is applicable in the case of non-absorbing crystals. In this article, equations are developed which relate the minimum values of the refractive and attenuation indices to those along the optic axis (longitudinal) and perpendicular to the optic axis (transverse). Also, for the first time, the longitudinal optical constants of graphite are given.

The optical properties of anisotropic absorbing crystals are characterized by their dielectric ( $\epsilon_{nm}$ ) and conductivity ( $\sigma_{nm}$ ) tensors. In the case of uniaxial or other crystals of high symmetry, the principal axes of the two tensors coincide. If we take the co-ordinate axes in the direction of the principal axes of the two tensors, Fresnel's equation may be broken into two factors<sup>1</sup>

$$\begin{aligned} (\mathbf{v}_p')^2 &= \mathbf{v}_x^2 \\ (\mathbf{v}_p'')^2 &= \mathbf{v}_x^2 \cos^2 \delta + \mathbf{v}_z^2 \sin^2 \delta \end{aligned} \quad (1)$$

where  $\mathbf{v}$  is the complex velocity defined by  $\mathbf{v}_p = c/\mathbf{n}$ ,  $\mathbf{v}_x = c/\mathbf{n}_x$ , etc.,  $c$  is the velocity of light,  $\mathbf{n}$  is the complex refractive index defined by  $\mathbf{n} = n(1 + i\kappa)$ ;  $n$  and  $\kappa$  are the refractive and absorption indices respectively; and  $\delta$  is the angle which the wave normal makes with the  $z$ -axis. The first equation applies when the electric vector is perpendicular to the principal plane, that is the plane formed by the optic axis  $z$  and the wave normal  $\mathbf{s}$ ; the ray is referred to as the ordinary wave. Its velocity is independent of  $\delta$ . The second equation applies when the electric vector lies in the principal plane and the ray is referred to as the extraordinary wave; thus light polarized in any other direction may be expressed in terms of these two equations.

From the first of equations (1) it follows that

$$n = n_x, \kappa = \kappa_x \quad (2)$$

In transforming the second into more useful forms, the case of weakly absorbing substances is generally considered, and it is assumed that the second power of the attenuation index may be neglected in comparison with unity<sup>1</sup>. This assumption leads to serious error in the case of graphite, especially in the ultra-violet. Replacement of the complex velocities by refractive and absorption indices leads to

$$\frac{\sin^2 \delta}{n_x^2 (1 + i\kappa_x)^2} + \frac{\cos^2 \delta}{n_x^2 (1 + i\kappa_x)^2} = \frac{1}{n^2 (1 + i\kappa)^2}$$

Separating the real and imaginary parts of the last equation we obtain

$$\begin{aligned} \frac{(1 - \kappa_x^2) \sin^2 \delta}{n_x^2 (1 + \kappa_x^2)^2} + \frac{(1 - \kappa_x^2) \cos^2 \delta}{n_x^2 (1 + \kappa_x^2)^2} &= \frac{1 - \kappa^2}{n^2 (1 + \kappa^2)^2} \\ \frac{\kappa_x \sin^2 \delta}{n_x^2 (1 + \kappa_x^2)^2} + \frac{\kappa_x \cos^2 \delta}{n_x^2 (1 + \kappa_x^2)^2} &= \frac{\kappa}{n^2 (1 + \kappa^2)^2} \end{aligned} \quad (3)$$

The physical significance of equations (2) and (3) is as follows. For the ordinary wave, the medium behaves like an isotropic material having an apparent refractive index  $n_x$  and absorption index  $\kappa_x$  regardless of the direction of the wave normal. For the extraordinary wave, the medium again behaves like an isotropic material with an apparent refractive index  $n$  and absorption index  $\kappa$  defined by equations (3). It is seen that  $n$  and  $\kappa$  are functions of  $n_x$ ,  $\kappa_x$ ,  $n_z$ ,  $\kappa_z$  and  $\delta$ . The determination of these apparent indices is strictly an experimental problem.

In the case of graphite, freshly peeled or cleaned basal planes serve as suitable surfaces for optical measurements<sup>2</sup>. At normal incidence reflectance becomes a property of  $n_x$  and  $\kappa_x$  and it is not necessary to employ polarized light. Reflectance using two immersion media is sufficient to measure  $n_x$  and  $\kappa_x$ . If an inclined face (for example, a 10 $\bar{1}$ 2 face, for which  $\delta = 57^\circ 49'$ ) is used with the electric vector perpendicular to the  $z$ -axis, the reflectance at normal incidence is the same as that from the basal planes. When the electric vector is rotated  $90^\circ$ , then  $n$  and  $\kappa$  determined are defined by equation (3). We now can evaluate  $n_z$  and  $\kappa_z$  using equation (3). If we let

$$\begin{aligned} p &= \frac{1 - \kappa^2}{n^2 (1 + \kappa^2)^2 \sin^2 \delta} - \frac{1 - \kappa_x^2}{n_x^2 (1 + \kappa_x^2)^2 \tan^2 \delta} \\ q &= \frac{\kappa}{n^2 (1 + \kappa^2)^2 \sin^2 \delta} - \frac{\kappa_x}{n_x^2 (1 + \kappa_x^2)^2 \tan^2 \delta} \end{aligned} \quad (4)$$

we obtain

$$\begin{aligned} n_z^2 &= \frac{1}{2} \frac{\sqrt{(p^2 + 4q^2)} + p}{p^2 + 4q^2} \\ \kappa_z^2 &= \frac{\sqrt{(p^2 + 4q^2)} - p}{\sqrt{(p^2 + 4q^2)} + p} \end{aligned} \quad (5)$$

Experiments by McCartney and Ergun yielded  $n_x = 2.15$ ,  $\kappa_x = 0.66$ ,  $n = 2.04$  and  $\kappa = 0.01$ . The value of  $\kappa$  is too low, because it leads to negative values of  $\kappa_x$  using equations (4). If we assume that the measured value of  $\kappa_x$  is correct and  $\kappa \approx 0$ , then  $\kappa$  would have a value of 0.08. This increase would correspond to an error of about 0.5 per cent in the intercepts of the straight line plot the authors obtained. It appears to be reasonable, therefore, to assume that  $\kappa_x$  is too small to be measured by simple optical procedures.

Table 1. THE OPTICAL PROPERTIES OF HEXAGONAL GRAPHITE AT 5461 Å

Optical property*	On the $x$ - $y$ plane	Along the $z$ (optic) axis
Refractive index, $n$	2.15	1.81
Absorption index, $\kappa$	0.66	Not detectable
Dielectric constant, $\epsilon$	2.61	3.28
Conductivity, $\sigma$	$1.68 \times 10^{11}$ sec. <sup>-1</sup>	Not detectable
Reflectance in air, $R$	0.280	0.083
Emissivity, $1-R$	0.720	0.917

\*  $\epsilon$  and  $\sigma$  are defined by  $\epsilon = n^2(1 - \kappa^2)$ ,  $\sigma = n^2\kappa$ .

The same argument may be extended to the conductivity along the optic axis. Using the above equations, the value of  $n_z = 1.81$ . In Table 1 are listed the optical properties of graphite at 5461 Å. Its optical anisotropy is rather marked.

# Chemiosmotic Hypothesis of Oxidative Phosphorylation

by  
PETER MITCHELL  
JENNIFER MOYLE  
Glynn Research Laboratories,  
Bodmin, Cornwall

Dr. Moyle and Dr. Mitchell answer criticisms of their interpretation of tests of the hypothesis proposed by Dr. Mitchell in 1961 to explain ATP synthesis in the inner membrane of mitochondria and of chloroplasts by a fuel-cell type of mechanism

Tager, Veldsema-Currie and Slater<sup>1</sup> have criticized our interpretation of measurements of the proton translocation to oxygen quotients ( $\rightarrow H^+/O$ ) observed during pulsed oxidation of succinate and  $\beta$ -hydroxybutyrate by rat liver mitochondria<sup>2,3</sup>. Their criticisms stem from two main points, one theoretical and the other experimental.

Their theoretical criticism is based on our finding (which appears to confirm an earlier observation discussed by Chance *et al.*<sup>4</sup>) that a certain amount of slack or "backlash" exists between the flow of oxido-reducing equivalents through the respiratory chain and the initiation of respiratory control in rat liver mitochondria isolated by an orthodox procedure<sup>2</sup>. We attributed this backlash to the presence of a limited number of charged particles (probably including calcium ions) which can move across or within the mitochondrial cristae membrane, so that the establishment by the respiratory chain system of the controlling membrane potential across the membrane would be delayed to an extent stoichiometrically related to the quantity of movable charge. Slater *et al.* say that the existence of such a backlash effect would be "difficult to reconcile with the fact that oxidative phosphorylation operates at maximal efficiency at very high ratios of  $[ATP]/[ADP] \cdot [P_i]$  and with the relative inefficiency of ATP compared with a functional respiratory chain in reversing the respiratory chain". We used the mechanical term "backlash" with the deliberate intention of making it easier to appreciate that, as in a machine (such as a bicycle with a fairly slack chain), the efficiency of energy transmission is usually independent of the backlash once this has been taken up<sup>3,5</sup>, but that there is little opposing force within the slack region of the backlash. According to our reasoning<sup>2</sup>, proton translocation stoichiometries can be measured accurately only when the conditions are so arranged as to "minimize the unknown extent of back flow or exchange of  $H^+$  ions and  $OH^-$  ions across the membrane system"; the forces contributing to the back flow should be minimal within the backlash region, and hence the choice of this region for our investigations.

The more serious criticism by Slater *et al.* stems from experiments intended to check ours. We described<sup>2</sup> a routine procedure for measuring  $\rightarrow H^+/O$  quotients in rat liver mitochondria by injecting pulses of oxygen (as air-saturated 150 mmolar potassium chloride) into anaerobic mitochondrial suspensions in a medium containing 150 mmolar potassium chloride, 3.3 mmolar glycylglycine and 2 mmolar substrate at 25° C, and recording the pH with a sensitive glass electrode system. Usually we used quantities of oxygen in the pulse corresponding to some 1  $\mu g$  atom of oxygen/g mitochondrial protein, and we observed  $\rightarrow H^+/O$  quotients approaching 4 and 6 with succinate and  $\beta$ -hydroxybutyrate, respectively, as substrate—indicating that one oxido-reduction cycle of nicotinamide-adenine dinucleotide (NAD) was accompanied by the translocation of two protons.

Slater *et al.*<sup>1</sup> say that in experiments "carried out in exactly the same way as described by Mitchell and Moyle", oxidation of reduced nicotinamide-adenine dinucleotide (NADH) did not occur with  $\beta$ -hydroxybutyrate as substrate unless ADP was added to the mitochondrial suspensions. This statement is based on: (a) chemical estimations of NAD, using perchloric acid to stop the oxido-reduction reactions; and (b) estimations of the transition from NADH to NAD *in situ* in mitochondrial suspensions using an Aminco double beam spectrophotometer. They could not detect significant oxidation of NADH by their chemical procedure with oxygen pulses of some 5  $\mu g$  atom oxygen or more per gram mitochondrial protein.

Incidentally, the backlash limit corresponds to 2  $\mu g$  atom of oxygen in our experiments<sup>3</sup>. Using the Aminco double beam spectrophotometer, however, they observed that the decline of the absorbance difference  $A_{340-374} m\mu$  could have indicated the oxidation of NADH. Nevertheless, they rejected this interpretation because the decline of the absorbance difference,  $A_{340-374} m\mu$ , occurred even when oxygen was added in the presence of rotenone, which blocks the oxidation of NADH in the respiratory chain. They concluded that the absorbance change, with  $\beta$ -hydroxybutyrate as substrate in the absence of rotenone, must result from oxidation of the cytochromes<sup>1</sup>. We are unable to accept that the Aminco traces of their Fig. 3, plotted without absorbance or time scales, and showing no absorbance maxima, constitute sufficient evidence to warrant the conclusion that no NADH oxidation occurs.

In Fig. 1 we show some measurements of the time-course of absorbance differences ( $A_{340-374} m\mu$ ) observed with an Aminco double beam spectrophotometer during routine oxygen pulse experiments<sup>2</sup> using  $\beta$ -hydroxybutyrate as substrate. The experiments represented by Fig. 1a were done with normal rat liver mitochondria, but in those in Fig. 1b, respiratory chain-linked NADH oxidation was blocked by the presence of 25  $\mu g$  rotenone/g mitochondrial protein. The oxygen pulses in the Fig. 1 experiments corresponded to 0.73  $\mu g$  atom of oxygen/g mitochondrial protein.

Referring to the curves of Fig. 1, if the absorbance decrease  $A_{340-374} m\mu$  shows oxidation of respiratory pigments, the presence of the rotenone evidently inhibits the reduction of the oxygen pulse. It is therefore concluded that there is a reduction of oxygen under the conditions of these experiments which is sensitive to rotenone; and it follows that a substrate, presumably the  $\beta$ -hydroxybutyrate, is oxidized by way of an NAD-linked dehydrogenase sensitive to rotenone. By observing oxido-reduction of cytochrome  $a$ , using the absorbance difference,  $A_{605-630} m\mu$ , and by simultaneous oxygen electrode measurements, we have confirmed that the oxygen pulse is virtually reduced to completion in less than 2 sec in the normal mitochondrial suspensions of Fig. 1a,

but that it takes about 30 sec in the mitochondria inhibited by rotenone (Fig. 1b).

The trace of Fig. 1a for  $A_{340-374} \text{ m}\mu$  appears to consist of a fast initial spike and a slower more persistent component. We therefore suspected that the traces might represent changes in more than one respiratory carrier. In particular, we suspected that the carrier causing the fast and relatively stable absorbance difference of the mitochondria inhibited by rotenone in Fig. 1b might not be the same as the carrier causing the slower absorbance change in the normal mitochondria of Fig. 1a. We investigated this possibility by making repeated absorbance difference measurements with a fixed reference wavelength (374 m $\mu$ ) but changing the test wavelength ( $\lambda$ ) so that differences in the speed of absorbance change at different wavelengths might be shown up and difference spectra might be plotted (Fig. 2).

In Fig. 1, the initial spike—which is more prominent at  $A_{315-374} \text{ m}\mu$  than at  $A_{380-374} \text{ m}\mu$  in the normal mitochondrial suspension—indicates the oxidation of a pigment that returns towards the reduced state about 1 sec after the oxygen pulse. The changes of absorbance of this pigment are approximately synchronous with the oxido-reduction of cytochrome *a*. The biphasic character of the absorbance changes is particularly clear in the curve for  $A_{315-374} \text{ m}\mu$  in Fig. 1a. On the other hand, as indicated by the curves of Fig. 1b, the absorbance changes observed in the mitochondria treated with rotenone show no evidence of complexity at any wavelength pair in the range 305–374 m $\mu$ . Accordingly, difference absorbance spectra  $A_{\lambda-374} \text{ m}\mu$  of the pigments oxidized at 0.5, 1, 2, 4, and 10 sec after the oxygen pulse in normal mitochondria and those treated with rotenone are shown respectively in the plots of Fig. 2. The extinction due to NAD is virtually zero for the range 305–374 m $\mu$  and therefore the standard absorbance spectrum is equivalent to the absorbance difference spectrum for the transition from NAD to

Fig. 2. Absorbance difference spectra ( $A_{\lambda-374} \text{ m}\mu$ ) obtained from traces corresponding to the samples shown in Fig. 1. Plots (i)–(v) show the spectra for normal mitochondria at time 0.5, 1.0, 2.0, 4.0 and 10.0 sec, respectively, after the oxygen pulse. The curves drawn through the points are composed of the curves of plots (vi) and (vii) as explained in the text. Plot (vi) is the spectrum obtained over the time interval 0.5–30 sec for mitochondria inhibited with rotenone. Plot (vii) is minus the standard absorbance spectrum ( $A_{374-\lambda} \text{ m}\mu$ ) of NADH obtained by adding 37.5  $\mu\text{mole}$  NADH to steady state anaerobic mitochondrial suspensions (32.0 mg mitochondrial protein) for various values of  $\lambda$  under the conditions of the experiments of Fig. 1a.

NADH. A comparison of the curves of plots (vi) and (vii) shows that the pigment oxidized in the mitochondria inhibited with rotenone has a difference absorbance spectrum (with a maximum near 320 m $\mu$ ) that is easily distinguished from that of the transition from NADH to NAD. In the normal mitochondria, however, it is evident that the difference absorbance spectrum at 0.5 sec closely resembles that of the mitochondria inhibited with rotenone, but that during the following period this gives place to a spectrum approximating more and more closely to that of the transition from NADH to NAD. In order to analyse

the plots (i)–(v) we have drawn through the experimental points curves which are composed of the curves shown in plots (vi) and (vii). The composite curves have been drawn by scaling the absorbance values for the transition from NADH to NAD (plot (vii)) and the “320 m $\mu$  pigment” (plot (vi)) so that their sum gives what we have judged to be the best fit on the experimental points. The proportions of the two absorbance spectra which contribute to a given composite curve are described in terms of the percentage of the total absorbance at 340 m $\mu$ , so that the percentage absorbance arising from the NADH to NAD transition can be estimated in each case. The percentages of absorbance at 340 m $\mu$  which corresponds to the NADH to NAD transition in the curves of plots (i) to (v) are respectively as follows: 25, 47, 75, 88, 100, corresponding to the state at 0.5, 1, 2, 4 and 10 sec after the oxygen pulse. It will be noted that the fit of the curves on the points is good except in the case of the 0.5 sec plot. This may have been affected by a stirring artefact in our system.

The data of Fig. 2 can be used to obtain the approximate time-course of the absorbance at 340 m $\mu$  corresponding to the “320 m $\mu$  pigment” and as a result of the transition from NADH to NAD as shown in Fig. 3, in

Fig. 1. Time-course of absorbance differences ( $A_{\lambda-374} \text{ m}\mu$ ) observed with an Aminco double beam spectrophotometer (cell light-path 1 cm). The mitochondria (32.0 mg protein) were suspended in a stirred anaerobic medium (18 ml.) containing 150 mmolar potassium chloride, 3.3 mmolar glycyl-glycine and 2 mmolar  $\beta$ -hydroxybutyrate at 20° C, with (b) or without (a) the addition of 25  $\mu\text{g}$  rotenone/g mitochondrial protein. At the time marked by the arrow, 23.5 mmg atom of oxygen was injected as air-saturated 150 mmolar potassium chloride, and the optical absorbance, shown in the figure, the pH and the oxygen tension were monitored simultaneously. The wavelength pair for which the absorbance difference was measured is indicated on each trace, and an upward deflexion denotes a decrease of absorbance.

Fig. 3. Approximate time-course of oxidation and reduction of the "320  $m\mu$  pigment" (○) and of the NADH (●) in normal (—) and rotenone-treated (---) mitochondria shown in terms of the partial absorbance changes due to either pigment at 340  $m\mu$ .

the normal mitochondria and those treated with rotenone. Using the standard absorbance of NADH described by Fig. 2 (vii), a decrease of 0.01 on the absorbance scale of Fig. 3 can be shown to represent the oxidation of 0.55  $\mu$ mole NADH/g mitochondrial protein. In the mitochondria treated with rotenone the "320  $m\mu$  pigment" rapidly achieves a steady state of oxidation, and there is no change in absorbance corresponding to the transition from NADH to NAD. In the normal mitochondria, the peak of oxidation of the "320  $m\mu$  pigment" occurs about 0.5 sec after the oxygen pulse, and it decays rapidly; whereas, the NADH oxidation commences comparatively slowly, is maximal between 2 and 4 sec, and returns to about half the maximal value by 10 sec after the oxygen pulse. The amount of NADH oxidized at 2 sec in the normal mitochondria is 0.58  $\mu$ mole/g mitochondrial protein, and the curve appears to rise slightly above this value. The oxygen pulse in these experiments corresponded to 0.73  $\mu$ g atom of oxygen/g mitochondrial protein. Bearing in mind that the oxidation of NADH and its subsequent reduction do not occur as separate consecutive processes but overlap to an extent depending on the approach of the system to a steady state, the present results indicate a very satisfactory transfer of reducing equivalents through the respiratory chain from NADH (or  $\beta$ -hydroxybutyrate) to oxygen under the conditions of our routine experiments.

The time-course of the oxidation of NADH in Fig. 3 is in keeping with the fact that the liberation of protons in the outer (suspension medium) phase is virtually complete by 5 sec after the oxygen pulse under these conditions. The subsequent, slower reduction of the NAD by the  $\beta$ -hydroxybutyrate would not, according to the chemiosmotic hypothesis, influence the pH of the outer phase.

Slater *et al.*<sup>1</sup> have suggested that the apparent failure of the mitochondria to oxidize NADH under the conditions of their experiments is due to loss of various components during the preincubation period. We have no reason to suspect that any such functionally destructive changes occur during our experiments, even for anaerobic incubation times as long as 60 min.

It is, of course, difficult to copy experimental techniques in every detail, and it may be that, to some extent, the criticisms that Slater *et al.* have levelled at our work can be attributed to their failure to pay sufficient attention to certain technical points. For example, mitochondrial damage may result from insufficiently strict anaerobiosis during preincubation; and such damage might have impaired NADH oxidation in their experiments. On the other hand, it seems distinctly possible that NADH oxidation did occur in the experiments of Slater *et al.*<sup>1</sup>, but that they have so far failed to measure it.

The results described here provide strong support for our earlier interpretation that, using oxygen pulses of some 1  $\mu$ g atom oxygen/g mitochondrial protein, two of the six proton equivalents translocated during  $\beta$ -hydroxybutyrate oxidation by rat liver mitochondria are accounted for by a rotenone sensitive region (Site 1 or Loop 1) of the respiratory chain, associated with NADH oxidation, which is not utilized in the oxidation of succinate.

We thank Dr. D. E. Griffiths and the Science Research Council for the use of an Aminco double beam spectrophotometer.

## Selecting Synchronous Populations of Mammalian Cells

by

S. E. PFEIFFER  
L. J. TOLMACH

Committee on Molecular Biology, and the Edward Mallinckrodt Institute of Radiology, School of Medicine, Washington University, St. Louis, Missouri

A method is described by which large synchronous cultures of mammalian cells can be obtained. Applied to HeLa cells, the method produces unperturbed populations of viable cells

SYNCHRONOUSLY growing populations of mammalian cells have been obtained by two general approaches. One involves the blocking and accumulation of cells in a particular stage of the division cycle, followed by release of this block<sup>1-12</sup>. Such a population has been termed, in the case of bacteria, a synchronized culture<sup>13,14</sup>. Low temperature

treatment<sup>1</sup>, serum starvation<sup>2</sup>, inhibition of DNA synthesis with ensuing accumulation of cells at the end of the pre-DNA synthesis ( $G_1$ ) phase by means of a variety of agents<sup>3-11</sup>, and temporary inhibition of mitosis by colchicine, with subsequent gathering of the inhibited cells<sup>12</sup>, have been used in this fashion. The normal physiology

Fig. 1. Effect of 0.03 µg/ml. vinblastine on the progression (DNA synthesis and cell division) of synchronously growing HeLa cells. Zero h represents the time of collection of mitotic cells. Symbols represent: <sup>14</sup>C-thymidine incorporation into untreated control cells (○) and cells treated with vinblastine from 3 to 16 h (■); relative cell number (70 to 100 cells present at the first reading) for control cells (○), cells treated from 3 to 20.75 h (▲), and cells treated continuously from 3 h onward (▼); mitotic index in cells treated continuously from 3 h (Δ); and survival (four experiments) on treatment from 3 h until the time at which the point is plotted, for cells growing in N16FCF (◇) or N16HHF (◆).

of the cells, however, is affected to varying degrees during the process of synchronization by these methods (see refs. 3 and 4).

The second method of obtaining synchronously growing populations involves selection of a group of cells in or close to a particular stage of the division cycle, without altering their metabolic state. These populations have been termed synchronous<sup>13,14</sup>. For example, gentle shearing forces have been used to either collect<sup>15-17</sup> or remove<sup>18</sup> the more loosely attached mitotic cells from monolayer cultures, and high specific activity tritiated thymidine has been used selectively to kill cells synthesizing DNA so as to leave alive only a "window" of cells in the latter part of the *G*<sub>1</sub> phase of the division cycle<sup>19</sup>. These methods suffer from certain shortcomings: the mitotic cell collection method is limited by the relatively small fraction of cells that is in mitosis at any instant in a randomly dividing population; the mitotic removal method presumably requires frequent rinsing of the monolayer over a protracted period; and although the tritiated thymidine method can yield large populations, they are contaminated with dead or damaged cells, making most biochemical studies impossible<sup>19</sup>.

In this paper we present a method of obtaining large synchronous populations of mammalian cells that are free of dead cells. A population growing at random is exposed to the drug vinblastine sulphate<sup>20</sup>, a potent inhibitor of cellular proliferation that exerts its action through metaphase arrest<sup>21-23</sup>, at a concentration that completely blocks the passage of cells through mitosis. The drug is applied for a predetermined period of time, shorter than the doubling time of the culture. As a result, any desired fraction of the population can be accumulated in mitosis and subsequently washed away<sup>15</sup>, leaving behind cells in only the latter part of the division cycle. After a portion of the remaining cells is allowed to pass through mitosis in the absence of the drug, vinblastine is again added to arrest further division, the drug treatment being continued this time for a period less than that required for the first cells in the window to progress to the next mitosis. The vinblastine and cells accumulated after the second addition are then removed, the window of cells now being sharply defined on both the leading and trailing edges. It may be noted that the time at which the window is formed after the first addition of vinblastine may be selected at will.

Although it has been reported that vinblastine acts at the biochemical level as an inhibitor of the conversion of glutamic acid to both urea and citric acid cycle intermediates<sup>24</sup>, Bruchovsky *et al.*<sup>25</sup> have reported that in mouse *L* cell populations, only the mitotic cells are affected by the drug. Since the usefulness of the method depends

on this specificity for mitotic cells, experiments were first designed to confirm these results with HeLa S3 cells. This test with HeLa was considered important as the ever present possibility that a given agent will act differently on different cell lines has recently been confirmed; the agent hydroxyurea, which promptly kills Chinese hamster cells in the DNA-synthetic (*S*) phase of the division cycle<sup>10,26</sup>, is without toxic effect on HeLa cells in this phase<sup>27</sup>, even though it inhibits DNA synthesis equally well in the two cell lines.

HeLa S3 cells were maintained as monolayers in medium N16HHF by conventional methods<sup>28</sup>. Synchronous populations for studying the interphase effects of vinblastine were obtained by the mitotic cell selection procedure<sup>15</sup>, using modifications already discussed<sup>29</sup>. All experiments were carried out in medium N16FCF<sup>27</sup> unless otherwise stated. Small volumes (10–20 µl.) of <sup>14</sup>C-labelled thymidine (0.05 µc.; 33 mc./mmole), uridine (0.1 µc.; 230 mc./mmole), or leucine (0.2 µc.; 198 mc./mmole) were added to cultures at 37° C for pulse (10–30 min) labelling of DNA, RNA, or protein, respectively, in order to determine rates of macromolecular synthesis. At the end of the labelling period, the growth medium was withdrawn and the cells were prepared for measurement of incorporated radioactivity in either of two ways. (a) (Fig. 1, Table 1): The cultures were quickly rinsed twice with buffered saline and fixed with acetic acid-ethanol (1:3) for at least 30 min. Cultures labelled with <sup>14</sup>C-uridine were fixed in this way and then washed twice with 0.2 N perchloric acid for at least one hour per wash, all at 4° C. Finally, the culture dishes were rinsed with 70 per cent ethanol and air dried, and the bottoms were punched out for counting in a low-background gas-flow counter. (b) (Fig. 2): The cultures were rinsed twice with buffered saline at 37° C, and treated for 4 min with 0.03 per cent trypsin D1<sup>28</sup>. The trypsinized cells were washed into a tube with cold buffered saline, and an equal volume of cold 20 per cent trichloroacetic acid was added to the tubes. Microscopic examination of stained plates revealed quantitative removal of the monolayer cultures by this trypsinization procedure. After at least one hour at 4° C the cells were collected on 'Millipore' HA filters on which they were washed twice with cold 10 per cent trichloroacetic acid, twice with cold 70 per cent ethanol, and twice with cold diethyl ether, and then air dried for counting as in (a). Cell division was monitored by repeated microscopic observations of delineated fields<sup>30</sup>; only cells that had progressed past telophase were considered divided. Cell survival was determined by scoring colonies containing 50 or more cells after 10–14 days of incubation. Vinblastine sulphate was dissolved in double distilled water and stored at –20° C

Fig. 2. Cell division and DNA synthesis in a synchronous population of HeLa cells selected by treatment with vinblastine. Zero time represents the first removal of the drug. The arrows indicate the readdition (↑) and subsequent removal (↓) of vinblastine. Open circles: relative cell number (124 cells present at the first reading) for cells treated from –17 to 0 h, and from 5 to 18 h; closed circles: total relative cell number, including cells arrested in mitosis after the readdition of vinblastine (see text); triangles: incorporation of <sup>14</sup>C-thymidine (30-min pulses).

until just before use. A calculated volume of 100-fold concentrated stock solution was added to a culture to obtain the concentration desired. To remove the drug, the medium containing vinblastine was withdrawn, the culture was rinsed once with fresh medium, and fresh, pre-conditioned medium was replaced.

Table 1. RATE OF PROTEIN AND RNA SYNTHESIS IN SYNCHRONOUS VINBLASTINE-TREATED AND CONTROL HELA CULTURES

Precursor	Time after addition of vinblastine (h)	Rate of incorporation (counts/min)	
		Control	Treated
<sup>14</sup> C-leucine	2	18	20
	10	23	26
	1	95	94
<sup>14</sup> C-uridine	3	104	100
	5	101	99

Vinblastine (0.03  $\mu$ g/ml.) was added to synchronous cultures 3.75 h after collection of mitotic cells. The rates of incorporation of radioactively labelled precursors into protein and RNA are expressed as c.p.m. incorporated per culture during a 20 (leucine) or 10 (uridine) min period of incubation. Each incorporation value represents the average of two or three plates.

Preliminary experiments indicated that vinblastine concentrations of 0.03  $\mu$ g/ml. completely blocked cells from passing through metaphase, while concentrations greater than 0.05  $\mu$ g/ml. caused crenellation of the cell membrane along with some loss of viability in cells exposed only during interphase. The lower concentration was therefore used in subsequent experiments.

Fig. 1 shows the effect of vinblastine treatment on DNA synthesis and on cell division. When added to synchronous cultures 3 h after mitosis, the kinetics of DNA synthesis is unaffected; the passage of cells into and through this phase is seen to be the same in the presence (closed squares) as in the absence (open squares) of the drug. When treatment was continued for 20.75 h, 10 per cent of the cells originally gathered had entered the next mitosis and had been arrested. These metaphase cells (as well as those in prophase and perhaps late  $G_2$ ) were only tenuously attached to the dish, and were easily removed from the culture, along with the vinblastine, by washing. After removing the drug, there was a lag of about 1.5 h in the treated culture before the number of cells (closed triangles) began to increase at the maximum rate. This was the time necessary for the first cells to progress through mitosis to cytokinesis. Thereafter, cell number increased in parallel with the control (open circles), levelling off when about 80 per cent of the cells had divided (compared with about 90 per cent division in the control culture). The effect of still longer treatment with vinblastine is also shown in Fig. 1: the mitotic index curve (open triangles) is seen to be parallel to, but 1.5 h ahead of the control cell number curve until about 27 h, while the number of cells (inverted triangles) remained constant. Thereafter, both cell number and mitotic index decreased as the arrested cells became so loosely attached that they spontaneously detached from the dish. It may be concluded that in the presence of concentrations of vinblastine that produce complete mitotic arrest, cells progress through interphase at the normal rate.

The ability of cells to form colonies after being exposed to vinblastine was also tested. The drug was added to cells 3 h after collection, and removed at various times thereafter; the cells were then incubated to allow formation of colonies. Viability (Fig. 1, diamonds) of cells exposed to vinblastine during interphase (3–18 h) is not decreased appreciably, if at all. The number of colony-formers is reduced only when cells are allowed to accumulate in mitosis before the drug is removed together with the accumulated cells.

Finally, the effect of vinblastine on the rates of protein and RNA synthesis in interphase cells was measured at various times after addition of the drug. The data in Table 1 show that at the drug concentration used here, these rates are not affected. A report<sup>21</sup> indicating that vinblastine inhibits RNA and protein synthesis in ascites tumour

cells *in vitro* involves drug concentrations greater by a factor of  $10^3$  to  $10^4$ . The relevance of those findings to the present experiments is therefore obscure.

These experiments with HeLa cells confirm the limitation of vinblastine action to the arrest of cellular progress at mitosis<sup>26</sup>. They show, in addition, that vinblastine does not affect the interphase rates of synthesis of protein or RNA. Because of uncertainty in their data, Bruckovsky *et al.*<sup>25</sup> cautiously stated that inhibition occurred "at or near" mitosis. The present work cannot eliminate this uncertainty as the resolution of the synchronous system is limited. This uncertainty in the precise point at which inhibition occurs does not, however, affect the usefulness of vinblastine for selecting synchronous populations.

Fig. 2 illustrates the application of vinblastine-induced inhibition of mitosis to obtain synchronous populations of HeLa cells. Randomly dividing populations growing in Petri dishes were treated with 0.03  $\mu$ g/ml. vinblastine for 17 h. The cells accumulated in mitosis were then washed away, and after rinsing the plate once with fresh medium to facilitate quantitative removal of the vinblastine and arrested cells, pre-conditioned medium was added to the plates. Incubation was continued for 5 h until most of the cells had divided, and then a second treatment with vinblastine was given in order to close the window. The drug was allowed to remain in the culture for 8 h this time, to trap the cells that only slowly progressed to mitosis. It was then removed, together with the laggards.

Fig. 2 shows that the first time the drug was removed the cell number increased sharply as the window of cells progressed through mitosis, 83 per cent of the original population dividing over the next 5 h (circles). The second treatment with vinblastine at this time caused cell division to cease. When the cells accumulated in mitosis after the second addition were counted as divisions and added to the cell number, it was found (closed circles) that cells continued to enter mitosis slowly over the next 8 h. A plateau was finally attained at a relative cell number of about 1.9. The cell number remained nearly constant for 18 h, when the second wave of division began. (The increase in relative cell number of 0.02 shown between 13 and 17 h, after removal of the second dose of the drug, is due to the initial division of a few very slow cells, not to the second division of rapidly progressing cells.)

The data in Fig. 2 serve to characterize further the synchronous population in several ways. First, the median doubling time, estimated from the time elapsed between the half-wave points of the cell number curve, was about 21 h. This is the doubling time of a randomly dividing population under these growth conditions. Second, DNA synthesis (triangles) underwent a 20-fold increase in rate subsequent to the very low level which obtained for 6 h immediately after removal of vinblastine. This increase, caused by cells entering  $S$ , is typical of the increase observed with mitotically synchronized cells<sup>14</sup>. The period from zero time to the onset of DNA synthesis at 6 h constitutes the minimum  $G_1$  time. Third, the degree of synchrony, calculated by the method of Engelberg<sup>32</sup>, was about 68 per cent for the first wave of division and approximately 39 per cent for the second wave. The decay in synchrony during this single cycle is in close agreement with that predicted by the theory of Engelberg (ref. 33, Table 4) which assumes that decay is due to random variation in generation time among the cells in the population. Analysis of time-lapse cinemicrographic data yields a standard deviation of generation times of 3.0 h (unpublished data).

This method of synchronization suffers from two principal limitations: it is restricted to monolayer cultures, and the degree of synchrony is less than can be obtained with a method in which the entire population is accumulated at essentially one point. Although the degree of synchrony can be improved by narrowing the window of cells, the size of the population is thereby

reduced, as it is directly proportional to the width of the window.

A potential third limitation, selection of the most slowly progressing cells, is easily overcome. The existence of such cells is shown by the slow attainment of a plateau in cell number after the vinblastine was removed (Fig. 2, closed circles). The last of these cells divided more than 30 h after the first addition of the drug (contrast with the mean doubling time of 21 h). In the method described here, nearly all of the slow cells are eliminated by a second application of the drug. Another solution would be to add high specific activity thymidine<sup>19</sup> at the time of removal of vinblastine, so as to kill cells still synthesizing DNA. This approach has been used successfully to purify a pre-mitotic ( $G_2$ ) population obtained originally from the mitotic cell collection method<sup>24,25</sup>. In general, however, secondary addition of vinblastine is to be favoured because the cells in question are thereby easily removed. It must be noted, finally, that neither of these approaches for eliminating cells which progress slowly can remove cells which do not progress at all. In this strain, plating efficiency is high (90–100 per cent), and non-progressing cells are not an important factor. They could be numerous enough to interfere, however, if the method were used with a cell strain in which an appreciable fraction of the population was constantly losing the ability to divide, but not to metabolize.

The method of synchronization described here has two principal advantages over the methods previously described. First, large populations can easily be obtained, the size being determined by that of the original culture of randomly dividing cells (which can be as large as desired, for example, Blake bottles with confluent layers of cells<sup>17</sup>) and the width of the window, which can also be adjusted to any size which is convenient. Second, the synchronous cells are relatively unperturbed, and are uncontaminated by dead, damaged, or metabolically altered cells. The method therefore is suitable for biochemical studies.

Certain of the survival data in Fig. 2 are from experi-

ments performed by Dr. B. Djordjevic<sup>24</sup>. This work was supported by a research grant from the U.S. Public Health Service. Mr. Pfeiffer is a trainee supported by a U.S. Public Health Service training grant.

## Preleukaemic Syndrome in Germfree AKR Mice

by  
MORRIS POLLARD

Lobund Laboratory, Department of  
Microbiology, University of Notre Dame,  
Notre Dame, Indiana

Some mice of the AKR strain reared under germfree conditions become thin and "hunched up", with rough wet fur, depilation around the anus, shrunken thymus and enlarged lymph nodes. The histological appearance of the thymus and lymphoid tissue is similar to that in the early stages of mouse leukaemia

OVER the past 5 years we have maintained and propagated six strains of laboratory mice through numerous generations under germfree conditions. Apart from the anatomical and physiological alterations usually found in germfree mice, the reproductive rate, litter size, weight gain with maturation, life expectancy and general appearance of the germfree mice are similar to those of the conventional animals from which they are derived. In all the germfree mice which were examined, the caeca were enlarged and thin-walled; and the reticuloendothelial systems were small and relatively dormant<sup>1-4</sup>. The lymph nodes and spleens were small; but occasional germinal zones were detected in them. The intermediate zones<sup>5</sup> were relatively free from cells, and contained primarily reticulum cells. Serum globulin levels were quantitatively less than half those of the conventional counterparts<sup>6,7</sup>. The size and morphology of the thymus glands in the maturing "germfree" animal resembled those of their conventional counterparts<sup>8</sup>. Virus-like

particles have been found in thymic tissues of representative mice of our six germfree strains; and lymphatic leukaemia was induced in mice of all strains by repeated whole body exposures to small doses of X-rays<sup>9-11</sup>. In addition to the leukaemia syndrome induced by X-rays, some germfree *C3H* and *Balb/c* mice developed spontaneous mammary adenocarcinoma, in which "B" type virus particles were observed<sup>12</sup>. Therefore while germfree mice can be considered free of fungi, bacteria, and pleuropneumonia-like organisms (PPLO)<sup>12,13</sup>, they are not free from virus. The designation of the mice as "germfree" is admittedly a misnomer but it is used here to indicate the conditions under which they live.

In contrast to the six strains of germfree mice referred to here, a strain of germfree AKR mice was derived in this laboratory from animals provided by Dr. John Trentin of Houston, Texas. Germfree AKR mice also carried leukaemia-like virus particles in the thymic cells; and significant numbers of them developed lymphatic leuk-

aemia spontaneously between 4 and 11 months of age<sup>14</sup>. The leukaemic lesions in germfree and in conventional *AKR* control mice were indistinguishable. A peculiar syndrome was noted among some of the germfree *AKR* mice which might have relevance to the leukaemic disease which most of them were destined to develop.

In addition to the structural and physiological alterations which were usually associated with germfree status, and the development of spontaneous lymphatic leukaemia, some of the germfree *AKR* mice developed an additional syndrome (referred to as "puny" disease) which has not yet been observed among the conventional *AKR* mice, or in other strains of germfree mice. At an average age of 118 days (range 48-374 days), fifty-five of the germfree *AKR* mice appeared "hunched-up" and thin; they had rough wet fur, and some depilated and irritated areas around the anus. Eventually, such animals died. Each mouse which showed this syndrome was removed from the germfree enclosure, killed by ether anaesthesia, and subjected to thorough autopsy examinations. The thymus glands were reduced in size, usually to the extent that they were difficult to detect. The lymph nodes were enlarged at least two to four times, but the spleen sizes were usually within normal limits. The lymph nodes of disease-free *AKR* mice were usually enlarged at least twice compared with other strains of germfree mice. No other grossly visible lesions were noted. Tissue specimens were fixed in Bouin solution embedded in paraffin, sectioned and stained with haematoxylin and eosin for microscopic examinations. Control tissues were prepared from germfree mice without symptoms and from *AKR* mice which had been exposed to the microbial flora of the clean animal room.

The most prominent histological alterations were noted in the thymus and in the lymph node tissues: the thymuses in thirty-nine of forty-seven mice examined were very much reduced in size. The thymic cortex was shrunken and depleted of small lymphoid cells (thymocytes) and mitotic figures were not apparent (Fig. 1). The medullary areas contained epithelioid cells, fibrocyte-type cells, and Hassell corpuscles.

In all the fifty-five sick mice, the lymph nodes were larger than those usually encountered in mice of other germfree strains. The nodes contained extensive aggregates of lymphoid cells in the regions of the primary follicles in which germinal or reaction zones were seldom observed. The intermediate zones were enlarged and fused with the medullary areas which contained markedly increased numbers of plasma-like cells: distinct cells with clear, slightly basophilic cytoplasm in which the nuclei were located eccentrically. In many of the lymph nodes the solid cords of plasma cells caused distension of the medullary structures (Figs. 2 and 3).

The spleens of disease-free germfree mice contained small foci of lymphoid cells which were surrounded by

Fig. 1. Thymus gland from mouse with "puny" disease. The cortex is depleted of thymocytes. ( $\times 28.5$ .)

Fig. 2. Enlarged lymph node from mouse with "puny" disease. The intermediate and medullary zones are swollen with cells. ( $\times 18$ .)

Fig. 3. Higher magnification of lymph node medulla of Fig. 2. Plasma-like cells distend this area. ( $\times 150$ .)

distinct perifollicular envelopes of reticulum-like cells, but the envelopes were thicker than those described by Krumbhaar<sup>15</sup> in the spleens of conventional rats. Germinal zones were rarely observed and the red pulp was clearly delineated from the white pulp. In the germfree "puny" *AKR* mice already described, the structure of the spleen was altered considerably. The lymphatic foci were enlarged. The white pulp was not clearly delineated from the red pulp, and the latter was infiltrated with large lymphoid, plasma and reticulum cells which appeared to have migrated from the perifollicular envelopes. The latter were no longer distinctly identifiable.

Haematocrit determinations were run on heparinized blood specimens which were collected in capillary tubes from the periorbital plexus. The red blood cell columns were within the normal limits of 30-40 per cent. The white blood cell counts of sick *AKR* animals were within normal limits; and microscopic examinations of stained blood smears from them revealed no abnormality.

The syndrome described here has not yet been observed in conventional *AKR* mice. Some of the "puny" germfree *AKR* mice were brought into contact with the laboratory flora, in order to determine whether they were suffering from a nutritional disease. Unfortunately, this was only done with sick mice showing severe symptoms of disease, otherwise we would have been uncertain of the original diagnosis. They all died.

The clinical appearance of the "puny" mice resembled that of runt disease; however, several significant conditions described in runt disease were not observed in the former. "Puny" mice did not show hepatomegaly with necrotic foci<sup>16,17</sup>. They did not show splenomegaly<sup>18</sup>, the lymph nodes were not depleted of cells<sup>18,19</sup>, and they were not anaemic<sup>17</sup>. Germfree *AKR* mice developed the "puny" syndrome at 2-3 months of age, whereas experi-

mentally induced "runting" usually appeared within 30 days of birth<sup>17</sup>.

The disease described here has been observed only in germfree *AKR* mice. We could not calculate the incidence of disease in the germfree colonies, as animals were withdrawn at frequent intervals for other experimental procedures. It occurred in all the five generations of *AKR* mice which have been propagated under germfree conditions. It is probably not attributable to dietary factors as six of the seven strains of germfree and conventional control mice in our laboratory have been on the same steam-sterilized diet (501° C) and 'San-i-cel' bedding for several years; and they were all maintained by the same procedures. Of all the seven germfree mouse strains examined, the *AKR* strain is the only one which has developed significant levels of lymphatic leukaemia spontaneously. One germfree Swiss-Webster mouse has developed spontaneous leukaemia during the past 5 years. The depletion of thymocytes observed in the "puny" *AKR* mice has been found in mice of all strains, after exposures to leukaemogenic doses of X-rays. The spontaneous thymic depletion may represent a stage in the development of leukaemia, which for some reason has not been clinically apparent in conventional *AKR* mice. The thymic tissues of four "puny" *AKR* mice were mostly shrunken and depleted of thymocytes; but the cortex contained some distinct hyperplastic areas of large lymphoblastic cells, with numerous mitotic figures among them. The latter areas resembled foci of leukaemic cells. In such animals the lymph nodes contained masses of plasma cells arranged as thick perivascular cuffs, and numerous well defined germinal zones. Siegler and Rich<sup>20</sup> described the early stages of leukaemia as atrophy of thymic tissues; and state that unilateral enlargement of the thymus is the initial lesion of leukaemia. Thymic atrophy was observed in "puny" mice, but at that stage of the disease unilateral enlargement of the thymus was not a remarkable occurrence. In germfree *C3H* mice, which had been inoculated with Gross virus at birth and which were thereafter examined at intervals, the leukaemic lesions developed in lymph nodes as irreversible hyperplasias of the germinal zones<sup>21</sup>,

and with increased numbers of plasma cells in the medullary areas. The plasma cells did not appear to be functional, as serum globulin levels remained low. Serum specimens from several germfree leukaemic *AKR* mice were examined by paper electrophoresis. The sera did not contain components in excess of those usually detected in sera from germfree mice. On the basis of accumulated observations leukaemia seems to be a manifestation of aberrant immunogenic function<sup>21,22</sup> and the syndrome described here in germfree *AKR* mice may be a reflexion of that condition. The depletion of thymic tissues and the hyperplasia of plasma cells in the lymph nodes may represent a prodromal stage of leukaemic disease. Histological evidence of transition from the depleted to the leukaemic thymus has been observed. We have no causative evidence for this spontaneous thymic depletion.

This investigation was supported in part by funds from the U.S. Public Health Service.

## Mediators of Acute Inflammation in Leucocyte Lysosomes

by  
AARON JANOFF  
SONJA SCHAEFER

Department of Pathology, New York  
University School of Medicine, New York

It may be that a substance from polymorphonuclear leucocytes attacks mast cells and releases histamine into the area of inflammation

A CHIEF characteristic of inflammatory reactions is a sustained elevation in the permeability of small blood vessels which develops several hours after the initial increase in permeability has disappeared<sup>1-4</sup>. In certain forms of injury, this delayed phase is often accompanied by the appearance of emigrated polymorphonuclear (PMN) leucocytes in the tissues; nevertheless, the mechanisms of the permeability and cell responses are generally considered to be independent<sup>5-7</sup>.

We have already reported<sup>8-11</sup> the immediate increases in the permeability of small blood vessels in the rat mesentery, skin and cremaster muscle which appear after local injection or application of microgram quantities of an enzyme-free basic protein extracted from the lysosomes of exudate PMN leucocytes. In the rat the effect of this fraction on vascular permeability results, at least in part, from the fragmentation of tissue mast cells

by the PMN factor<sup>10</sup>. A basic protein isolated from eosinophilic leucocytes has recently been shown to exert similar effects<sup>12</sup>.

Although most previous work fails to support the suggestion that mast cell histamine or serotonin is responsible for the delayed change in permeability during inflammation<sup>13-15</sup>, or that a causal relationship exists between tissue leucocytosis and this phase of the reaction, the observed capacity of leucocytic cationic polypeptides to induce mast cell degranulation may have an *in vivo* counterpart in inflammation. It was therefore felt that the *in vitro* mastocytolytic action of this agent warranted further analysis.

We have compared the *in vitro* mastocytolytic action of lysosomal cationic polypeptides with that of compound 48/80, a known liberator of histamine, and with that of other naturally occurring and synthetic polycationic

polypeptides. In addition, we have compared the actions of these polycations on mast cells *in situ* with their effects on free mast cells.

PMN lysosomal polypeptide (LPP) was prepared as previously described<sup>9</sup> and stored in lyophilized form after dialysis against Ringer-Locke salt solution. Compound 48/80 (Lot No. NS 280) was obtained from the Burroughs-Wellcome Research Laboratory. Arginine-rich and lysine-rich preparations of calf thymus histones were purchased from Worthington Biochemical Corporation. Poly-L-lysine hydrobromide was obtained in two degrees of polymerization (molecular weights 2,600 and 230,000) and another sample was obtained with a molecular weight of 20,000.

*In vitro* assays of the effects of these substances on rat mast cells were carried out using morphological criteria of degranulation. Two types of mast cell preparation were used. Mesenteric mast cells were processed according to the method described by Norton<sup>16</sup>. Mesentery fragments were incubated for 30 min in Ringer-Locke glucose solution buffered with bicarbonate to pH 7.45 and containing known concentrations of test agents. Ringer-Locke alone was always included to provide a control test for spontaneous rupture of mast cells. Tissues were fixed in 10 per cent formalin containing 0.1 per cent toluidine blue, dehydrated in acetone, cleared in xylene, mounted in 'Permount' and examined under the microscope. Completely intact mast cells were counted as were those showing any degree of granule extrusion. In each experiment, the mean values of percentage disruption for each test agent were based on an examination of 1,500 cells. The alternative assay procedure involved incubating rat peritoneal mast cells with the test agents. In this case, free mast cells (along with other peritoneal leucocytes) were first deposited on 'Millipore' filter membranes with an average pore diameter of 5 $\mu$ , according to the technique of Lagunoff and Benditt<sup>17</sup>. The membranes were afterwards processed in exactly the same way as the mesentery fragments except that human serum albumin (Cohn Fraction V) was added to the Ringer-Locke in a concentration of 0.1 per cent to preserve the reactivity of the mast cells. In each experiment, the membranes were incubated in a solution containing 1  $\mu$ g/ml. of compound 48/80. This gave a further check on the responsiveness of the cells to degranulating agents. The second assay method, although less sensitive than the first, nevertheless has distinct advantages. First, all mast cells in any single experiment were obtained from one donor animal; and second, the test agents were free to act directly on the cells without any interference from components of the connective tissue ground substance.

Fig. 1 shows the log dose/response plots obtained when the percentages of mesenteric mast cells undergoing degranulation were determined for different concentrations of compound 48/80 and LPP. The results vary quite markedly over the middle range of doses but increase significantly at higher concentrations of the test agent. At intermediate doses, only a few granules are extruded and exact classification is difficult. At higher concentrations of degranulating agents, disruption of mast cells involves the extrusion of many granules and classification becomes easier. From such plots, the effective concentrations (or doses expressed as  $\mu$ g/ml.) required to produce degranulation in 50 per cent of the cells ( $ED_{50}$ ) can be calculated. The  $ED_{50}$  for compound 48/80 closely matches previously reported<sup>18</sup> values for this same lot (NS 280) and is about one-twelfth the  $ED_{50}$  of LPP on a simple weight/weight basis. Obviously, a more accurate comparison of the relative effectiveness of these two materials requires a pure preparation of the active PMN agent and more precise knowledge of its molecular size in order to make comparison with 48/80 on a molar weight basis. Preliminary information on the probable molecular weight of LPP has been obtained by gel-filtration chromatography. These experiments show that the mast cell active agent is completely retarded in 'Sephadex G-25'

and G-15 gels when chromatography is carried out in an acetate-water buffered solvent system at pH 4.0. Thus, our previous estimate of an approximate molecular weight of 10,000 for LPP<sup>10</sup>, based solely on the behaviour of this material during dialysis, was far too high. This aspect of the problem is discussed in greater detail elsewhere<sup>18</sup>.

Table 1 compares the degranulation of rat mesenteric mast cells produced by LPP with that produced by several other naturally occurring and synthetic polycations. It can be seen from the table that LPP is considerably more effective than calf thymus histones (both arginine-rich and lysine-rich preparations) as well as poly-L-lysine (especially polymers with molecular weights of 20,000 or more). Two possible explanations for this effect were considered in further detail.

One interpretation is that the relative effectiveness of these agents depends largely on their molecular weights and that in terms of molar concentrations the agents might prove more nearly equal in their effects. This interpretation is supported to some extent by Fig. 2, in which the reciprocals of the molecular weights and  $ED_{50}$  values of the agents tested are plotted logarithmically. The biologically active oligomer of compound 48/80 has a molecular weight of 600 (ref. 19). This is included in the comparison, but the histone preparations have been excluded because their molecular weights are not known exactly. We have assumed, on the basis of unpublished work, that the molecular weight of LPP is about 1,000. Fig. 2 shows that on the basis of these assumptions the logarithmic relationship between molecular weight and  $ED_{50}$  for these agents is, with one exception, reasonably linear.

An alternative explanation for the greater mastocytolytic activities of compound 48/80, LPP and the lower molecular weight poly-L-lysine could be based on the greater ability of these agents to penetrate the barrier of polyanionic substances (chondroitin sulphuric acid and

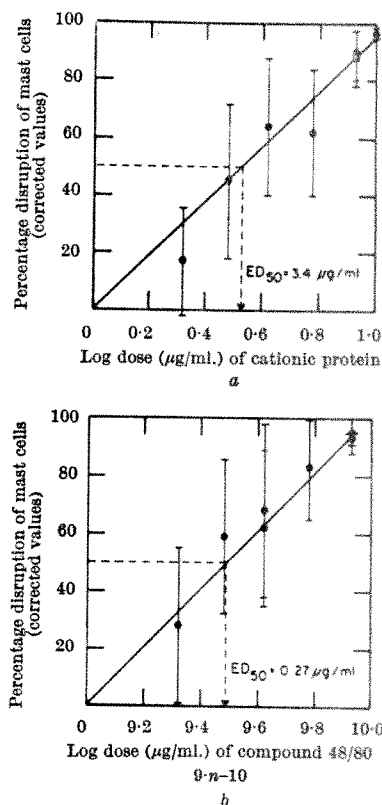

Fig. 1. Quantitative comparison of effects of LPP and 48/80 on rat mesenteric mast cells *in vitro*. Log dose/response plot for LPP (a) and compound 48/80 (b). Percentage degranulation at each concentration has been corrected for spontaneous cell breakage by subtracting the control value of corresponding experiment (Ringer-Locke value). Calculated  $ED_{50}$  values are shown in the figure.

\* Percentage disruption is based on the number of mast cells showing any degree of granule extrusion ( $\times 640$ ). Each value represents 1,500 mast cells examined.

† Approximate effective dose disrupting 50 per cent of mast cells.

Fig. 2. Relationship between molecular weight of test agent and ED<sub>50</sub> value of the agent when tested on rat mesenteric mast cells *in vitro*. Individual agents are identified within the figure.

other acidic mucopolysaccharides) which surrounds the mesenteric mast cells *in situ*. According to this view, histones and larger molecular weight poly-L-lysines would be more readily trapped through the formation of charge-linked complexes with the acid polymers (as suggested by Dr. Ira Green) than would LPP or low molecular weight poly-L-lysine, while 48/80 would be least affected by this interaction. We carried out experiments to test this interpretation.

According to the latter hypothesis, calf thymus histones and high molecular weight poly-L-lysines ought to have effects more nearly equal to those of LPP when they are tested on mast cells which have been stripped of their surrounding connective tissue barriers. For this purpose, we used preparations of free peritoneal mast cells, washed and deposited on 'Millipore' filters. The data in part A of Fig. 3 show that such preparations did in fact respond to agents which had not affected mast cells *in situ*. Thus, poly-L-lysine (molecular weight 20,000), at a concentration which produced no degranulation of mesenteric mast cells (10  $\mu$ g/ml.), caused disruption of peritoneal mast cells equivalent to that produced by LPP at the same concentration. Arginine-rich histone (10  $\mu$ g/ml.) also exerted a moderate effect in this test system. Furthermore, as shown in part b of Fig. 3, the addition of 100  $\mu$ g/ml. soluble chondroitin sulphuric acid completely inhibited the mastocytolytic action of 10  $\mu$ g/ml. poly-L-lysine (molecular weight, 20,000); but, as expected, it did not significantly alter the effectiveness of LPP at the same concentration.

When chondroitin sulphuric acid was added to clear solutions of polycations, different degrees of turbidity

developed depending on the polycation used. Table 2 shows these results. Apart from polylysine of molecular weight 2,600, which also produced a significant turbidity, those polycations which had been effective degranulators of mesenteric mast cells, and which remained effective against free mast cells in the presence of chondroitin sulphuric acid, were not precipitated by the latter substance to the same degree as the high molecular weight polylysines. The concentration of polycation and chondroitin sulphuric acid was the same for all agents tested. To the extent that turbidity in this system reflects the formation of large, insoluble complexes between cationic and anionic polymers, these data support the interpretations put forward earlier.

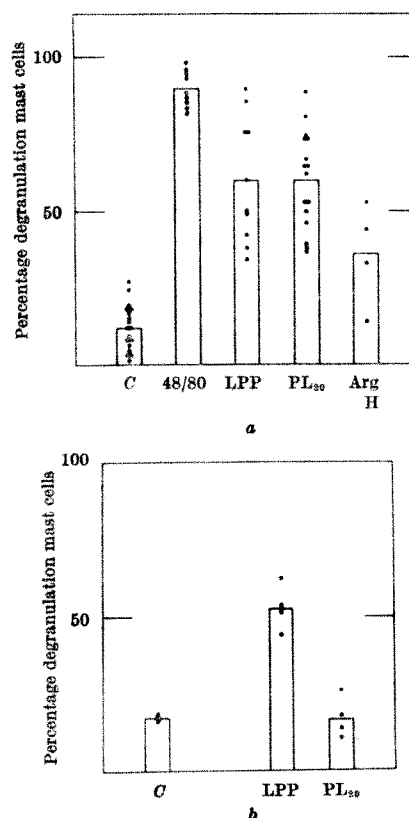

Fig. 3. Effects of 48/80 (1  $\mu$ g/ml.), LPP (10  $\mu$ g/ml.), poly-L-lysine (molecular weight 20,000) (10  $\mu$ g/ml.), and arginine-histone (10  $\mu$ g/ml.) on free rat peritoneal mast cells deposited on 'Millipore' membranes. Agents are identified in the figure. (C, Ringer-Locke control.) a, Agents tested alone; b, agents tested in the presence of chondroitin sulphate (100  $\mu$ g/ml.).

† 1.0 mg/ml. concentration.

‡ O.D.<sub>520</sub> against water of cation or of chondroitin sulphate alone is zero.

These results lead us to suggest that the effectiveness of LPP against mast cells *in situ* may to some extent be due to its relatively low molecular weight (and therefore correspondingly high molar concentration at standard test doses). A further basis for its activity clearly lies in its failure to form insoluble or irreversible complexes with chondroitin sulphate and presumably other acid mucopolysaccharides of the connective tissue ground substance. Thus, LPP has the physical-chemical properties required for a high degree of biological activity as a mastocytolytic agent in connective tissue, in which inflammation actually proceeds. This component of exudative PMN leucocytes deserves further consideration as a potential endogenous liberator of histamine, although it remains to be shown that it is a natural mediator of inflammation.

## Morphological Changes in the Adrenal Glands of Wild Rabbits

by  
K. MYERS

C.S.I.R.O. Division of Wildlife Research,  
Canberra

The physiological condition of Australian wild rabbits, *Oryctolagus cuniculus*, is accompanied by changes in the adrenal glands which may, in particular, be helpful in studying "the pathology of overpopulation"

Christian<sup>1,2</sup>, Chitty<sup>3,4</sup> and Calhoun<sup>5,6</sup> have stimulated many ecologists to examine critically what Christian calls "the pathology of overpopulation". The activity of the adrenal glands is a prominent factor in this pathology, and as part of a comprehensive programme of research into the ecology of the wild rabbit, intensive observations are consequently being carried out on changes in the adrenal glands and other organs in relation to density, sex, age, season, social status, reproductive condition and health, in four natural populations of rabbits in widely different climatic regions, and in experimental populations confined within large enclosures and managed under conditions similar to those described earlier<sup>7</sup>.

Sampling will continue until 1966 when more than four thousand rabbits will have been examined. The analysis of the data will not be completed until 1967. In the light of modern interest in this field it seems appropriate to describe briefly the type of information that has been collected from a study of the adrenals taken from the first fifteen hundred animals.

**Seasonal Changes in Adrenal Weight.** There is a well marked and significant seasonal rhythm in adrenal weight and size, with a peak in the winter and a trough in the summer. The fluctuations occur in both sexes and in all regions and bear no direct relationship to age, breeding or behaviour. They may be of metabolic significance. The seasonal fluctuations in weight of rabbit adrenals are of the order of 30–50 per cent, and appear to be restricted to variations in the amount of cortical tissue.

The mean weights of adrenal glands from sub-tropical and sub-alpine areas are 30 per cent greater than those taken in hot, arid areas and warm, temperate regions.

**Histological Changes.** Changes in histology and size occur without relation to changes in adrenal weight. Histological changes accompany reproduction, stress, ill-health, mineral deficiencies and certain other as yet undefined stimuli.

The "resting" adrenal gland of healthy sub-adult rabbits consists of a narrow glomerular zone, usually 20–30 per cent of the cortex and devoid of lipid; a broad dense fasciculate zone with narrow radial strands two cells wide and containing very abundant lipid; and a narrow lipid-filled reticulate zone of packed clumps of cells arranged in alveolar manner about the medulla. Strands of reticulate zone cells often project into the medulla. The inner parts of the radial fasciculate strands merge imperceptibly into the clumped cells of the reticulate zone (Fig. 1).

Sexual maturity is marked by an almost total loss of lipid from the clumps of cells surrounding the medulla, and a partial loss from the inner third of the fasciculate zone, probably caused by the onset of sex hormone secretion.

**Reproduction.** With the start of the breeding season, the cells in the fasciculate strands abutting the reticulate zone hypertrophy and become clumped and indistinguishable from those in the reticulate zone proper, except for the higher lipid content of the latter.

In females, as the breeding season progresses, and apparently with successive pregnancies, the interface between reticulate and fasciculate zone moves progressively outwards, with the fasciculate cells clumping up in advance of the wave. Degeneration of the clumped cells follows and the lipid coalesces to form large extracellular masses of lipid or ceroid tissue occupying large vacuoles (fatty vacuolation<sup>8</sup>; spontaneous vacuolar degeneration<sup>9</sup>; possibly akin to ceroidogenesis<sup>10</sup>) (Fig. 2).

Masses of new cells now appear at each end of the medulla, apparently associated with connective tissue components, and the degenerating tissue appears to be obliterated by an active phase of regeneration which also moves outwards behind the active fasciculata-reticularis interface.

In young females (<25 months) large extracellular vacuoles rarely occur, for the lipid disappears quickly after

Fig. 1. Section of adrenal gland from a sub-adult male rabbit showing medulla, and reticulate and inner fasciculate zones. Lipid is present in abundance in both cortical zones ( $\times 100$ ).

Fig. 2. Section of adrenal gland of adult female rabbit (26-33 months old) during breeding season, showing large masses of lipid surrounding the medulla (lower right) and large extracellular vacuoles containing orange-coloured lipids along the old fasciculate strands. The fasciculata-reticularis interface is at the top of the photograph ( $\times 100$ ).

formation. In older females, on the other hand, extracellular lipid is common and remains for longer periods of time. In very old females ( $> 33$  months) the vacuoles become very large and masses of lipid often surround the medulla, almost cutting it off from the cortex. It is also common in old females to find islands of old cortical tissue near the medulla which have been isolated by irregular patterns of regeneration, sometimes well within the fasciculate zone.

In males fatty vacuolation is less spectacular and the fasciculata-reticularis interface does not move far into the fasciculate zone. Moderately severe cases of fatty vacuolation are seen only in very old males.

The whole process appears to form a regular cycle of regeneration of adrenal tissue and is intimately connected with reproduction.

**Psychological Stress.** The rabbit is not easily stressed physically<sup>11</sup>. Adrenal weight decreases during starvation,

together with most other organs of the body. There is a marked adrenal response, however, to psychological stresses, occasioned by increased friction, which occurs as population density increases<sup>12</sup>.

Adrenal glands from rabbits in experimental populations of high density show a typical histological picture, with minor variations related to social status and health. The clumps of cells in the reticulate zone hypertrophy and become compact, and the clumping process moves outwards along each strand of the fasciculate zone, often reaching the fasciculata-glomerulosa interface, each strand taking on a ropy appearance (Fig. 3).

The glomerular zone becomes narrow, forming only 5 per cent of the cortex, and lipid accumulates along the capillaries between the glomerular whorls giving the interface a ragged appearance. In extreme cases lipid increases in the glomerular zone, the individual glomerulae

Fig. 3. Section of adrenal gland of adult male rabbit from a high density population showing fasciculate strands completely composed of clumped cells. Medulla is situated to lower left ( $\times 100$ ).

Fig. 4. Section of adrenal gland from adult female rabbit from sub-alpine region showing large glomerular zone occupying almost half the cortex, and commencement of nodular hyperplasia (see Fig. 7) at glomerulosa-fasciculata interface ( $\times 40$ ).

become clumped and the fasciculate zone breaks through to the capsule, apparently by reorganization of glomerular tissue. The glomerular zone is then left as festoons hanging from the capsule.

Unlike the changes described for reproduction the clumps of cells do not break down and extracellular vacuoles full of lipid are not formed. Reconstitution of the glomerular zone appears to occur by cell division from elements next to the capsule.

**Disease.** Adrenal glands from rabbits suffering from diseases of bacterial and viral origin (pasteurellosis, myxomatosis) show a lack of zonation, and narrow dense lipid-filled fasciculate strands fill the cortex from capsule to medulla. There is no clumping of cells.

**Mineral Deficiencies.** The glomerulosa-fasciculata interface is one of dynamic interplay between the two regions. The apparent ease with which the fasciculate zone replaces the glomerular tissue under conditions of stress and disease

Fig. 5. Soft wooden pegs presented to wild rabbits in the sub-alpine region at a time when adrenal glands of sampled rabbits display a hypertrophied glomerular zone. Rabbits avidly attack pegs soaked in NaCl and MgCl<sub>2</sub> solutions, lightly attack pegs soaked in KCl and hardly touch pegs soaked in FeCl<sub>3</sub>, CaCl<sub>2</sub> and distilled H<sub>2</sub>O. Pegs are 0.75 in. square.

Fig. 6. Adrenal gland of adult male rabbit from sub-tropical region showing large cortical nodule on surface of gland ( $\times 8$ ).

Fig. 7. Adrenal gland from adult male rabbit from sub-tropical region showing nodular hyperplasia at glomerulosa-fasciculata interface. Note normal narrow glomerular zone, almost devoid of lipid ( $\times 40$ ).

Fig. 8. Adrenal gland from adult male rabbit from sub-tropical region showing cortical nodule isolated from main adrenal by ingrowth of capsular tissue bordered each side by glomerular zone ( $\times 40$ ).

has already been mentioned. The glomerular zone also invades the fasciculate zone under certain conditions. This kind of activity is preceded by an unusual loss of lipid from the outer parts of the fasciculate zone and by an apparently heightened cell division along the interface, indicated by the appearance of numerous, small, darkly staining nuclei, and the presence of mitotic figures. In sub-alpine areas, adrenal glands in which the glomerular zone forms half the cortex are common at times (Fig. 4), and in all other regions studied—except the arid zone—dramatic changes in glomerular width occur. The main causes appear to be mineral deficiencies in pastures occasionally superimposed on the physiological drain of repeated lactations and possibly low temperatures<sup>13</sup>. The presentation at these times of soft wooden pegs permeated by different salt solutions leads to ravenous attack on those soaked in Na<sup>+</sup>, Mg<sup>++</sup> and K<sup>+</sup> salts (Fig. 5), particularly sodium chloride and sodium bicarbonate. Similar findings have been reported for ruminants<sup>14</sup>.

**Unknown Stimuli.** Another condition of equal interest is the formation of cortical nodules (Fig. 6). These have been found on adrenal glands of rabbits from all regions. They form at the interface of glomerular and fasciculate zones and are seen in sections as large hyperplasias forcing the two zones apart (Fig. 7). Further growth causes the adenoma to lift the surface of the adrenal, and capsular tissue grows inwards and beneath the nodule to cut it off from the adrenal body. Glomerular cells proliferate along each side of the invading capsular tissue and the accessory body, when isolated, consists of a small adrenal without medulla (Fig. 8). The accessory body may be thrown

Fig. 9. Adrenal gland from adult male rabbit from sub-tropical region showing three large accessory adrenals lying free in the body cavity. Each accessory adrenal consists of fasciculate and glomerular tissue only ( $\times 5$ ).

off to lie free in the mesenteries of the body cavity. The accessory adrenal, the surface of which is covered by a finely anastomosing pattern of blood vessels, is clearly a secreting gland when formed. In some cases several bodies may be formed simultaneously (Fig. 9). The data being collected suggest that after the stimuli causing their formation have passed, the size of accessory bodies

rapidly decreases. Three mass occurrences of the formation of accessory cortical bodies have been observed. In each case they appear to have resulted from sudden and excessive stimulation of both the glomerular and fasciculate zones at the same time. In a recent experiment a significant enlargement of the zona glomerulosa was produced in rabbits maintained on a sodium poor diet. Incipient nodulation occurred in three of these rabbits challenged with ACTH.

The observations described above suggest that the adrenal gland is a sensitive indicator of several physiological conditions in the wild rabbit and is a valuable organ for the ecologist to use in population analysis.

## Early Stimulation and Maternal Behaviour

by

S. A. BARNETT

J. BURN

Department of Zoology, University of Glasgow

Stimulating young mice by various methods can accelerate their development. Some of the changes evidently result from the direct action of the stimulation on the young, but some seem to be due to changes in the behaviour of the mother toward her offspring

COLONIES of several strains of laboratory mice (*Mus musculus*) can breed indefinitely in a room kept at  $-3^{\circ}\text{C}$ . They require only a standard diet, blocks of ice (which they lick, for water), and bedding such as cotton wool. Both inbred and genetically heterogeneous mice maintained in this way have progressively improved in reproductive performance over a number of generations. The improvement has been especially evident in a substantial decline in the death rate between birth and weaning<sup>1</sup>. There is no way evident of accounting for this by a genetical change in the inbred strains<sup>2</sup>; maternal effects, which might contribute to it, are therefore being sought.

By a "maternal effect" we mean any non-genetical influence of a female on her offspring. The development of a mammal reared in a cold environment may be influenced by (i) the direct action of the cold; (ii) the effects of the cold on (a) the uterine environment provided by the mother, (b) her milk secretion, (c) her behaviour in the nest—for instance, tending the young and nest building<sup>3</sup>. The way in which these factors operate is influenced by the genotype of both mother and young<sup>4</sup>. This article describes an exploratory study of the effects of (i) exposure to cold in early life, and (ii) alteration in maternal behaviour, on the development of mice.

### Experiments on Maturation and Breeding

Mice of the highly inbred strain, *A2G/Tb*, were kept in permanently mated pairs in a room at  $21^{\circ}\text{C}$  (ref. 5). Second to fourth litters were used, after reduction to five at the age of 6 days. One mouse in each litter was left in the nest from the sixth to the eleventh day inclusive,

and received no ear mark (control). One mouse had a hole punched in one ear, but was left also in the nest. The remaining mice were ear-marked and exposed daily, for 90 min/day, from day six to day eleven, either at  $34^{\circ}\text{C}$  (warm-exposed) or  $21^{\circ}\text{C}$  (cold-exposed). At the beginning of each period of exposure, all mice from each litter were placed by hand in a plastic box. From this they were lifted back to the nest or to their exposure boxes. At the end of the period, all mice were again put in the box before they were finally returned to their nest. Hence all the mice were handled to the same extent.

Mice of all classes were weighed at 6, 11 and 21 days, and females also at 35 days. Mice from each class were each subjected to the following tests. (i) From day eight all mice were tested for the Preyer (startle) reflex by exposure to a short, loud sound (handclap at 10 cm), and the day of its appearance was recorded. (ii) The first day on which both eyes were open was also recorded. (iii) Females were examined each day after weaning at 3 weeks, and the day of vaginal opening was noted. (iv) At 22 days males were transferred to a room kept at  $-3^{\circ}\text{C}$ , where they were put separately in metal cages with cotton wool bedding, and ice cubes instead of water.

At 35 days, females were put each with an adult male which had not been used for experiment. The reproductive performance of these mated pairs was recorded to include all litters born within 112 days of the birth of the mother. Each litter was removed from its parents at the age of 21 days.

The observations during this first group of experiments concern (a) indices of maturation, (b) reproductive performance.

Fig. 1. Percentages of male mice which survived exposure, alone, with bedding, to  $-3^{\circ}\text{C}$ , for 7 days from the age of 22 days. Numbers of mice exposed are shown in the rectangles.

There was no evidence of an effect on body weight of any of the treatments. Table 1 and Fig. 1 summarize the results of other tests of development. The effects of exposure of young mice to cold are included here, because the chance of survival in the cold is a function of age<sup>6</sup>.

Exposure outside the nest, whether to a warm or to a cold environment, had no effect on any of these four developmental features. None of the slight differences between the experimental classes (ear-punched only, warm-exposed and cold-exposed, respectively) even approached statistical significance. There was, however, in each case, evidence of an effect of ear-punching. The appearance of the Preyer reflex, and the opening of the eyes and the vagina, were each earlier in all the experimental groups than in the controls (that is, the only group whose ears had not been punched). A more marked difference was in survival on exposure to cold at the age of 3 weeks (Fig. 1): there was no evidence of an effect of previous exposure outside the nest; but few of the controls survived, while about half the experimental mice did so. Hence maturation was not, in these experiments, influenced by exposure to cold in early life.

By contrast, reproductive performance was substantially affected. This was most clearly shown in the survival, between birth and weaning, of the young of the cold-exposed females (Tables 2 and 3). The proportion of litters wholly lost by cold-exposed females was lower than that of any other group. Of the weaned litters, the largest at weaning were those of the cold-exposed females.

### Maternal Behaviour

Mated pairs similar to those of the first group of experiments were used. When a litter was 6 days old it was reduced to even numbers of each sex. The young were then divided into four groups as follows: group A had no ear mark; group B had two marks in the left ear; group C had one mark in the right ear; group D had one mark in the left ear. All the mice in any one litter were either of groups A and B, or of groups C and D. After day 6, mice of groups A and B were left undisturbed in their cages until weaning at 21 days; those of group D were placed alone in a box kept at  $34^{\circ}\text{C}$ , for 90 min/day from

Table 1. INDICES OF DEVELOPMENT, FEMALES: MEAN AGES, DAYS, WITH STANDARD ERRORS

	No. of mice	Preyer reflex	Eyes open	Vagina open
Controls	15	$13.1 \pm 0.19$	$13.3 \pm 0.17$	$26.4 \pm 0.33$
Ear punched only	13	$12.5 \pm 0.25^*$	$12.6 \pm 0.22^*$	$25.5 \pm 0.38^*$
Out of nest: warm	18	$12.5 \pm 0.20^*$	$12.6 \pm 0.17^*$	$25.6 \pm 0.33^*$
Out of nest: cold	18	$12.4 \pm 0.23^*$	$12.7 \pm 0.24^*$	$25.4 \pm 0.45^*$

\* Significantly different from controls ( $P < 0.05$ ).

Table 2. LOSSES OF WHOLE LITTERS

	No. of mated pairs	No. of litters	No. lost	Percentage lost
Controls	10	25	6	24
Ear-punched only	11	25	5	20
Out of nest: warm	17	45	10	22
Out of nest: cold	16	40	6	15*

\* Significantly different from controls ( $P < 0.05$ ).

Table 3. NUMBER OF YOUNG IN EACH WEANED LITTER: MEANS WITH STANDARD ERRORS

	No. of litters	Young/litter
Controls	19	$5.0 \pm 0.49$
Ear-punched only	20	$5.3 \pm 0.50$
Out of nest: warm	35	$5.3 \pm 0.29$
Out of nest: cold	34	$6.0 \pm 0.33^*$

\* Significantly different from controls ( $P < 0.05$ ). (Numbers of mated pairs as in Table 2.)

Table 4. INCIDENCE OF PARENTAL CARE. MEANS WITH STANDARD ERRORS

Class	No. of observation periods	Care: sec/5 min
A, Controls	10	$4.8 \pm 0.62$
B, Ear-punched only	10	$14.0 \pm 1.94^*$
C, Handled	7	$8.9 \pm 2.21$
D, Out of nest	7	$20.3 \pm 5.92^{\dagger}$

\* Significantly different from controls ( $P < 0.001$ ) and from handled ( $P < 0.05$ ).

$\dagger$  Significantly different from handled ( $P < 0.05$ ).

day 6 to day 11; mice of group C were handled as much as those of group D, but were returned to the nest instead of being exposed.

Parental behaviour was observed for periods of 5 min. The amount of contact (licking, nuzzling, biting and carrying) received from either parent by the two classes of young was recorded. These observations were made on days 6–10, inclusive, from birth.

The most important results of the experiments on maternal behaviour are summarized in Table 4. A nestling with a hole punched in its ear, but not otherwise different from a control, was likely to receive about three times as much parental attention as a control. Handling by an experimenter had no significant effect. The greatest amount of parental attention was given to nestlings which had had their ears punched and had also been exposed outside the nest.

Our observations illustrate the multiple effects of early stimulation already described by other workers. These may be put into four classes.

(i) Earlier maturation has been described in a number of investigations. Early exposure of infant rats or mice to cold can accelerate the development of thermo-regulation<sup>7</sup>; handling in early life increases the rate of deposition of cholesterol in the brain<sup>8</sup>, promotes earlier eye opening<sup>9</sup> and results in earlier development of the adult pattern of loss of adrenal ascorbic acid in response to adverse conditions<sup>10</sup>. (ii) Superior resistance to various adverse conditions has been reported in adults which had been stimulated in infancy. The "stressors" used have included immobilization<sup>11</sup> and deprivation of food and water<sup>12</sup>. Handling, too, has increased the survival rate of adult rats on exposure to stressful conditions<sup>13</sup>. (iii) Diverse changes in adult behaviour have been believed to result from early stimulation: in particular, handled animals have been said to be less "emotional", and more exploratory, than controls<sup>14</sup>. (iv) Finally, our own experiments give an example of an effect of early exposure to cold on the reproductive efficiency of females.

Not all the results of experiments have been consistent. Cowley and Widdowson<sup>15</sup>, for instance, in careful experiments on rats, failed to find the increase in body weight which had been believed to result from handling. Our own observations on gain in weight resemble theirs. Similarly, McMichael<sup>16</sup> did not observe an expected increased resistance to unfavourable conditions in animals handled in infancy; nor did Tobach and Schneirla<sup>9</sup> find an effect on "emotionality". Other conflicting evidence on behaviour has been given by Levine<sup>14</sup>, Weininger<sup>11</sup> and Eells<sup>17</sup>.

Some of the apparent contradictions may be due to differences of method. The kinds of stimulation used

have included handling, exposure to cold, shaking and electric shock. The age at which the stimulation is given is important; a recent example is given by Bell<sup>18</sup>.

Despite these difficulties, attempts have been made to find a unitary explanation of the effects of early disturbance. One possibly fruitful notion is that handling, exposure outside the nest and other treatments all constitute mild "stressors"<sup>14</sup>; that is, they activate the pituitary and adrenal glands in such a way that, it is supposed, this system becomes more efficient, and confers greater resistance in later life. Some workers have emphasized the role of the central nervous system. Bovard<sup>19</sup> has suggested that the primary effect of early handling should be sought in the cerebral cortex; the cortex, he supposes, acts on the hypothalamus and hence on the pituitary and other endocrine organs. Another sort of hypothesis is that early disturbance induces a generalized arousal through the reticular formation<sup>20</sup>; and Lát<sup>21</sup> has emphasized the possible role of early stimulation in permanently altering nervous function in general.

Our own observations, reported here, do not make possible any decisive contribution to a unitary theory. They lead us to emphasize the need for close scrutiny of the details of the conditions of each experiment. In particular, when nestlings are being investigated, the exact behaviour of the parents toward them needs to be recorded. Young<sup>22</sup> has come to a similar conclusion on the basis of observations on rats, and Ressler<sup>23</sup> from a study of fostered mice. There is already one notable example of the influence of maternal care on the development of the nervous system. Reyniers and Ervin<sup>24</sup> found it necessary to stimulate the skin of neonatal rats reared without females, if the reflexes of elimination were to develop; this cutaneous stimulation is normally provided when the mother licks her young just after birth. Čapek and his colleagues have confirmed this observation on mice<sup>25</sup>.

We believe that the marked effects of ear-punching in our experiments were due, not to any direct arousal or

stress, but to stimulation of the mother by the abnormal state of the ear. Ear-punching itself is over in a few seconds; but the mothers persistently, during several days, gave their ear-clipped young more attention than they gave the controls. Mere handling of the young, in our experiments, did not have this effect to a significant extent, though it may have had some influence on maternal behaviour. In fact, the incidence of parental care, directly observed, paralleled the effects we recorded, in the first series of experiments, on maturation. Perhaps there is a general influence of maternal attention on the development of the nervous system.

Human bones and implements in the Keilor Terrace of the Maribyrnong River, near Melbourne, provide new evidence of the antiquity of man in Australia

IN August 1965, Mr. Donald Mahon uncovered some bones while digging through consolidated river terrace silts in the Maribyrnong River Valley, near Melbourne. He considered this to be of interest and importance, and left the bones in place in the near vertical quarry face. One of us (T. A. D.) immediately visited the site, and collected a fragment of a frontal bone which consisted of a portion of the orbital plates, supraorbital margins, glabella, superciliary eminences and a few centimetres of the frontal squame. It was said to have been broken off by the front-end loader, and it was positively identified as human. Some portions of the face, thigh and leg bones were not evident, having been dislodged and perhaps damaged by the bucket of the loader, but most other bones appeared to be represented and in approximately normal relationship.

The skeletal remains were 4 ft. below the surface of a river terrace (at approximate river level (R. L.) 58 ft. 6 in.) and 10 ft. above the present floodplain (R. L. 48 ft.). The terrace forms part of the Keilor terrace in which a human cranium was found in 1940. The new discovery is approximately 2 miles south of this site, and is on the right bank of the Maribyrnong River near the junction

with Green Gully tributary (lat. 37° 44' south, long. 44° 50' east) and 1 mile south of the township of Keilor (Fig. 1).

Measures were immediately taken to safeguard the site, and, to ensure recognition of the authenticity of the discovery, scientists from Melbourne and Canberra were invited to inspect the bones in position before any excavations commenced. All agreed that the remains were overlain by undisturbed terrace deposits and accepted their authenticity.

The Director of the National Museum of Victoria initiated the recovery of the remains, to establish their stratigraphical and environmental context and to assess the archaeological significance of the site. We were invited to take responsibility for these aspects of the investigation, and other specialists were invited to contribute to the investigation of particular problems. A Keilor Project Committee was set up by the Trustees of the National Museum of Victoria to co-ordinate work in the area for which financial support has been provided by the Ian Potter Foundation and the Australian and New Zealand Bank.

Immediate excavation of the site of the remains confirmed that the upper 3 ft. of terrace sediment was un-

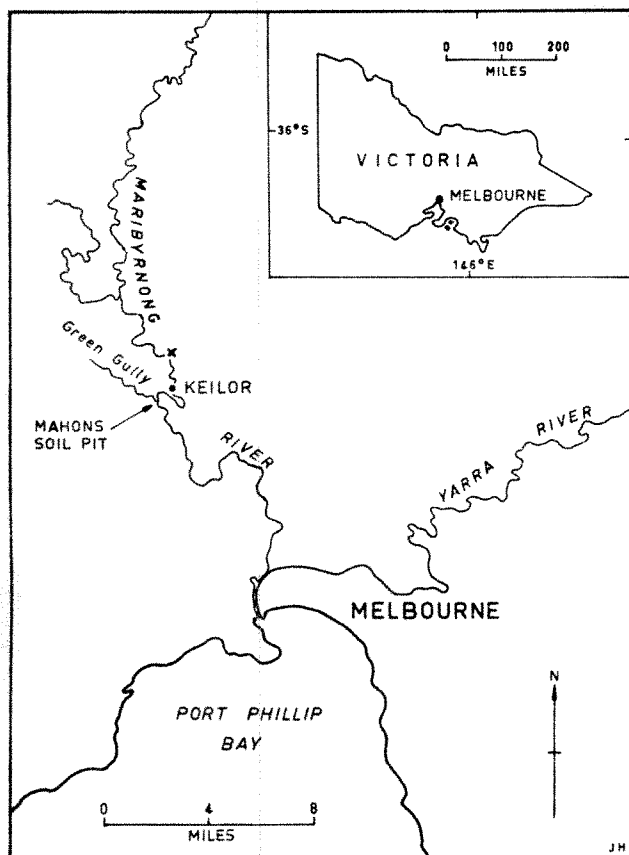

Fig. 1. Diagram showing the location of Mahon's soil pit near the junction of Green Gully and the Maribyrnong River near Keilor. The site of the cranium found in 1940, in the same terrace as the present skeleton, is marked by a cross.

disturbed, but a zone of soil disturbance immediately around and above the bones indicated that they had been buried in a shallow grave, about 12 in. deep. The appearance of the bones suggested a skeleton deposited on its left side with the legs semi-flexed at the hips and knees. Later work suggested that the bones could have been desiccated at the time of burial. The bones were fragile and fractured and no attempt was made to separate them *in situ*. As the earth was removed from above them they were painted with a strengthening solution of 'Bedacryl' in acetone and covered with several layers of tissue paper pasted on to protect them from the plaster of Paris used for reinforcement. The remains were removed in three blocks—the head, the trunk and limbs, and the feet. These three blocks were undercut, lifted and removed to the Museum. They were later transferred to the University of Sydney where a detailed investigation is being undertaken by Prof. N. W. G. Macintosh.

There are four terrace levels in this part of the valley, but only the two intermediate levels are present in the soil pit. The oldest (highest) and the youngest (lowest) of the four are not represented in the pit and are therefore not discussed here. The environmental history of the valley immediately before and after the burial has been reconstructed from detailed stratigraphic data. In this way the human bones and the burial horizon are seen as part of a complex sequence of events, a tentative outline of which is given below (see Fig. 2).

Deposition of gravels with medium to fine sands took place at the base of the Keilor terrace (zone A). A pause in aggradation followed with the development of a surface (near R.L. 42 ft.) with signs of extensive burning probably caused by bush or grass fires. Further deposition to 44 ft. occurred, followed by a longer pause with the development of a weak soil profile now shown by remnant

prismatic cleavage. Aggradation continued with deposition of fine sands and silts to near 60 ft. in the Keilor terrace. A long period of non-deposition followed, with intensive organic activity and soil profile development. The buried soil below 60 ft. is characterized by abundant infilled and now fossilized worm tubes, a high degree of organization of carbonate into vertical concretions, and a well developed soil structure (strongly developed vertical cleavage with differentiated soil units breaking down to good crumb). A period of stream incision followed, and part of the terrace sediment was eroded to form a steep cliff which delineated the edge of the river channel which existed at that time.

Accumulation of eroded sediment and soil occurred along the base of the cliff and worm tubes and carbonate concretions from the upper soil were reworked, to form zone B. Many trees grew along the steep aggrading river bank and these were burnt at intervals leaving massive charcoal deposits in zones of pink oxidized sediment and soil. Some of this was redistributed to produce bands of pink ochreous pellets through the steeply dipping marginal deposit (zone B) along the edge of the channel. Organic activity, similar to that in the Keilor terrace proper (below 60 ft.), continued in this zone and some weak reorganization of carbonate occurred to produce vertical concretions in areas previously burned by fires.

The burial of the Green Gully human remains occurred near a zone of burnt earth in Keilor terrace sediment. The material used to cover the body shows evidence of its disturbance in the intermingling of burnt and unburnt pellets of earth in random association, and in the loss of soil structure when compared with similar soil immediately below and around the walls of the shallow grave in the undisturbed zone.

Aggradation recommenced in the area, and the result was the deposition of 10 ft. of medium sands on the lower terrace (zone D channel sands) simultaneously with 3 ft. of finer overbank clayey sands on top of the Keilor terrace forming zone E. A later phase of stream incision occurred, after which deposition on the terrace surfaces ceased and soil profiles developed to their present condition. There is no evidence of intensive organic activity or of significant carbonate accumulation in material deposited after the burial of the Green Gully remains.

The grave was located close to the terrace contact and close to the steep slope which, at the time of the burial, formed the edge of the river channel. Evidence of the precise position of this slope was destroyed by the bulldozer, but reconstruction from the preserved stratigraphic detail shows that the grave was only a few feet west of the slope. There was charcoal and pink oxidized earth around and below the burial, burnt remains of trees which had grown along this slope. Soft pink oxidized earth had been partially used to infill the grave.

Radiocarbon dates have been obtained from two samples of charcoal collected from near the bones. These samples were from 3 ft. 6 in. below the body in the zone of charcoal associated with the burnt tree root, and from 1 ft. above the body, from charcoal redistributed along a horizontal bedding surface overlying the burial. Both samples were dated in the Institute of Applied Science at Melbourne and gave dates of 8,155 ( $\pm 130$ ) B.P. in both cases. (A thorough check of laboratory procedure has failed to provide an explanation for this remarkable coincidence of dates other than pure chance. Samples dated were collected by different workers on different days, to eliminate the possibility of mixing or incorrect labelling. The dates reported are the averages of three runs on each sample after rounding to the nearest 5 yr.)

The dates, consistent with the environment reconstructed above, represent the ages of charcoal from trees which grew on the same steeply sloping ground surface: the lower sample is from an *in situ* root and the upper sample is from charcoal redeposited by overbank deposition but derived from trees growing along the edge

Fig. 2. West to east composite section through Mahon's soil pit showing the stratigraphic interpretation of the area and the relative position of the skeleton. For detailed description see text.

of the channel. The postulated sequence of depositional events suggests that the skeleton may be a little younger than the carbon dates, but the coincidence of dates is a clear indication of the approximate age of the ground surface on which the trees grew and on which the bones were buried. Additional samples from representative zones through this sequence have been submitted for determination. These results, together with comprehensive laboratory analyses of soil and sediments, will throw more light on the stratigraphic and environmental history of the site.

Irrespective of the significance of the skeletal remains, the site is of considerable archaeological interest. Evidence for human activities is stratified sporadically through a depth of 25 ft. of the Keilor terrace and throughout the younger terraces. Several archaeological excavations have been carried out in different areas of the pit since August, under our supervision, and another was directed by R. V. S. Wright of the University of Sydney. The area immediately surrounding the grave has been trenched on three sides, the deepest trench reaching 14 ft. below the bones. Approximately 220 stone primary flakes and cores, mostly of quartzite, were recovered, over half of them coming from below the ground surface of the time of burial; in addition, ten flake artefacts were found bearing traces of secondary trimming and shaping. From other excavations nearby a large collection of stone flakes was recovered, particularly at depths from R.L. 61 ft. to R.L. 57 ft. The deepest sounding reached the base of the terrace, 27 ft. below the bones. The oldest artefacts consist of two quartzite flakes with distinct bulbs of percussion, at R.L. 44 ft. 6 in. and a possible quartzite core at R.L. 40 ft. 6 in. The lowest trimmed implement was found, however, at R.L. 55 ft. 6 in. It is important to observe that none of these artefacts was derived from elsewhere—flakes and cores have sharp edges.

Several arrangements of basalt pebbles, possibly hearths, were uncovered. Some contained faunal remains, although the total sample of animal bones from the excavations is meagre. The lowest presumed hearth was only 5 ft. from the grave, on an earlier occupation surface, just below R.L. 57 ft.

The trimmed artefacts found stratigraphically below the burial in all areas with the exception of Wright's trench include some which are merely retouched in nondescript fashion, but the majority are classifiable

under the genus "scraper". Varieties represented include side, end, concave and discoidal; no other implement types are represented. In the overlying deposit, the top-most 2 ft. contain small blades which are characteristic of a microlithic industry, although no actual backed blades were found at the locus of the bones. Elsewhere in the pit, however, microlithic blade cores, a geometric trapezoid microlith and broken blades with steep blunting retouch were located *in situ* in this upper deposit, together with three unifacially trimmed pebbles. These latter are fine specimens of a type well known in Australia, reminiscent of the Hoabhinian pebble tools of south-east Asia.

Wright's excavation also uncovered several scrapers, and, between R.L. depths 60 ft. and 57 ft., he also found delicately trimmed "thumbnail" scrapers and implements known in Australia as flake fabricators, many of which were made from white quartz. Current age expectations for these tools, based on evidence from New South Wales, would predicate a more recent date.

Archaeological evidence, with the exception of the qualifications introduced by Wright's work, therefore suggests that at Keilor until less than 8,000 yr ago flake implements of the "scraper" type were preferred. This is consistent with evidence from other parts of Australia. Broadly comparable types apparently constituted the sole stone tool kit used at Kenniff Cave, Queensland, during a period extending from 5,000 yr ago in Pleistocene times. The later appearance of microlithic techniques and uniface pebble tools in the Keilor sequence is also in conformity with carbon-14 dates for those industries elsewhere. The earliest dated occurrence of both industries is in north-eastern New South Wales, where they belong to the fourth and fifth millennia B.C., respectively. The cultural sequence at Keilor may, indeed, serve as an independent chronological indicator to confirm the stratigraphic inferences. Further excavations are projected.

Despite their poor state of preservation, these fragmented human bones presumably constitute, by some 2,000 yr, the oldest dated post-cranial skeletal remains of *Homo sapiens* known in the Australasian region. The Green Gully discoveries offer a unique opportunity for scientific collaboration, to ascertain the environmental conditions and cultural status of human occupation in late Pleistocene and in early post-glacial times.

## An Early Miocene Member of Hominidae

by

L. S. B. LEAKEY

National Museum Centre for Prehistory and  
Palaeontology, Nairobi, Kenya

Hitherto, the earliest fossils recognized as belonging to the Hominidae, from Fort Ternan and the Siwaliks, have been dated to the Mio-Pliocene. Discoveries in early Miocene deposits at Songhor and Rusinga, Kenya, have made it possible to carry the date of the separation of the true Hominidae from the Pongidae back to the Lower—or possibly Early Middle—Miocene

IN 1934, G. Edward Lewis<sup>1</sup> described a new genus of fossil primate from the Siwalik deposits in India under the generic name of *Ramapithecus*, with *brevirostis* as the specific name of the genotype. He emphasized that *Ramapithecus* possessed some hominid characters but classified it, in his official diagnosis, as a member of the family Simiidae, cautiously adding "(Hominidae?)". In 1938, Gregory and Hellman, in a joint paper with Lewis<sup>2</sup>, remarked about this genus: "While the Siwalik genus *Ramapithecus* and the South African *Australopithecus* are still apes, by definition, they are almost on the human threshold in their known anatomical characters".

In 1961, Elwyn Simons<sup>3</sup> stated that he believed that *Ramapithecus* might be a member of the Hominidae, but he did not make a definite claim to this effect. He regarded its geological age to be "within the Nagri zone, which is of Pliocene—early Middle Siwalik—age".

In 1961, I published<sup>4</sup> a preliminary note on what I considered to be a new genus and species of primate from Fort Ternan, Kenya. I named this *Kenyapithecus wickeri* and provisionally gave the geological age as Early Pliocene (Pontian in the English sense). Because the fossil fauna from the same site and level has become better known, I have more recently referred it to the Upper Miocene<sup>5</sup>. The fauna of Fort Ternan is rather more primitive than the Early Pontian fauna from such sites as Pikermi, Samos, etc. In my paper of 1961, I noted similarities between *Kenyapithecus wickeri* and *Ramapithecus brevirostis*, and mentioned its resemblance to the Hominidae. I left the familial position open, however, and described it as "Family, *incertae sedis*".

During the past few years, most authorities have come to agree that *Kenyapithecus wickeri* and *Ramapithecus brevirostis* should both be regarded as early representatives of the Hominidae. It is also widely accepted that both belong, geologically, to the closing stages of the Miocene and/or to the very early Pliocene. Evernden and Curtis<sup>6</sup> have indicated a potassium-argon date for the Fort Ternan deposits, which yielded *Kenyapithecus wickeri*, of about 14 million years. A glass fission track date can be expected soon.

Simons and Pilbeam<sup>7</sup>, as well as Simons<sup>8</sup>, have recently advanced the opinion that *Kenyapithecus wickeri* should be regarded as a synonym of *Ramapithecus brevirostis*. At the same time they have suggested that Pilgrim's *Dryopithecus punjabicus* is also identical. Because the name of this species has priority, they have proposed that the Mio-Pliocene representatives of the Hominidae should be known as *Ramapithecus punjabicus* (Pilgrim). In their view (p. 136), moreover, *Dryopithecus fontani* (partim), *Bramapithecus thorpei* and *Bramapithecus sivalensis*, as well as Woo's far eastern *Dryopithecus keyuanensis*, should now, also, be regarded as synonyms of *Ramapithecus punjabicus* (Pilgrim). This seems to be a somewhat extreme example of taxonomic lumping. Although it is possible—but by no means certain—that all the Asiatic

representatives listed may belong to the single genus *Ramapithecus*, the generic distinctiveness of the East African *Kenyapithecus* will be demonstrated in this article.

In my view, the species *Kenyapithecus wickeri* differs from the Asiatic forms at the generic as well as the specific level.

It must also be noted that although the original type of Lewis's *Ramapithecus brevirostis* came from the Nagri zone, which is usually regarded as of early Pliocene age, Pilgrim's *Dryopithecus punjabicus* was listed as from the Chinji formation, which is usually regarded as Uppermost Miocene rather than Early Pliocene. On the evidence of the palaeontological data which are so far available, both are probably geologically slightly younger than *Kenyapithecus wickeri* of Kenya.

In 1951 Le Gros Clark and Leakey<sup>9</sup> described a small maxillary fragment of a primate from site R.106 on Rusinga Island, Kenya, tentatively placing it in the genus *Sivapithecus* with *africanus* as a specific name. It was shown to differ markedly from any of the material representing the various species of *Proconsul* from Kenya, while it seemed to share certain features in common with some of the specimens which were described as *Sivapithecus sivalensis*. It was also regarded as differing from the genus *Dryopithecus* of Europe and Asia as described in the literature. This was a view based only on the small maxilla fragment which formed the Type, which came from deposits usually regarded as of Lower Miocene age.

In 1961 I suggested that when the time came to classify the primate which I had named *Kenyapithecus wickeri* into a zoological family it would have to be joined in that same family by *Sivapithecus africanus*. This view was supported at one time by Simons, for he wrote in 1963: "*Sivapithecus* apparently crosses the Mio-Pliocene boundary but is not easily separated from *Ramapithecus*, a conclusion indicated by Leakey's report". In his most recent work with Pilbeam, however, Simons has withdrawn from this view. He now treats all known *Sivapithecus* material as falling within the genus *Dryopithecus* with the name "*Sivapithecus*" reduced to sub-generic rank. He even goes so far as to claim that Le Gros Clark and Leakey's *Sivapithecus africanus* is both generically and specifically "identical" with *Sivapithecus sivalensis* of India. I shall endeavour to show that this cannot be the case.

There is thus a growing consensus of opinion that *Ramapithecus* and *Kenyapithecus* both represent primitive members of the Hominidae; if this is correct and as they were already present in India and East Africa respectively, in Mio-Pliocene times we should expect to find still earlier ancestral members of the family Hominidae either in Middle or even in Lower Miocene deposits. This could be either in Africa or in Asia or in both continents, and the origin of the family Hominidae may even be found to extend back to the Oligocene.

In consequence of pondering this idea, I recently began a detailed re-examination and re-evaluation of the large collection of Lower Miocene primates from Rusinga, Songhor, Koru, etc., which is in Nairobi. This resulted in an examination of some specimens which had been collected since the last study and others which had been overlooked previously, as well as a review of certain others which might have been wrongly identified in earlier publications. The report which follows deals with the recognition, within this collection, of a number of specimens which seem to me to be unquestionably representatives of the family Hominidae. All but one are, moreover, on geological as well as faunal evidence, older than both *Ramapithecus brevirostis* and *Kenyapithecus wickeri*. The specimens to be discussed come from deposits which are usually regarded as of Lower Miocene age, and they include the type specimen of what was formerly called *Sivapithecus africanus*. There is also one specimen from Maboko Island which is regarded as representing *Kenyapithecus sp. indet.*

### The Genus *Kenyapithecus*

FAMILY Hominidae  
GENUS *Kenyapithecus* Leakey 1961

My original diagnosis of the genus *Kenyapithecus* was as follows: "A genus within the Superfamily HOMINOIDEAE, with low crowned molars and premolars; the upper canines are small and set vertically in their sockets. There is a well defined canine fossa and the root of the malar element of the malar-maxillary process is set just above the first molar".

For purposes of comparison with both my 1961 diagnosis of *Kenyapithecus* and also with the revised diagnosis of the genus, which will be given later, Lewis's generic diagnosis of *Ramapithecus* is included in full. Similarly Simons and Pilbeam's new diagnosis of *Ramapithecus* will also be quoted in full.

Lewis's original diagnosis of *Ramapithecus* read as follows:

"Simiidae (Hominidae?) in which the dentition parallels the hominid type in its broader aspects. The dental arcade of the upper jaw is parabolic rather than "U" shaped as in recent Simiidae, and hence the palate broadens posteriorly. The cheek teeth of opposite sides of the jaw are more widely separated posteriorly than anteriorly rather than approximately equidistant from  $M^2$  to  $P^3$ . The face is very slightly prognathous, as contrasted with recent Simiidae. There are no diastemata in the dental series. The canine is small, not an antero-posteriorly elongated trenchant tusk, but of hominid type with a transverse dimension exceeding the antero-posterior dimensions."

In place of this generic diagnosis, Simons and Pilbeam have recently suggested the following:

*Ramapithecus* "Differs from *Australopithecus* and members of the *Dryopithecus* group in the following general features:

Slightly smaller overall size (except for *Dryopithecus africanus*) [by which they mean *Proconsul africanus* of other authors], shallower mandible, less complex patterns of tooth crenulation, little or no evidence of cingula or Carabelli's cusps and shorter face. Incisors and canines reduced in relation to cheek-tooth size when compared to *Dryopithecus* but not as markedly as in *Australopithecus*; incisor procumbency intermediate. Differs from *Dryopithecus* and other apes in showing more widely spaced and much lower molar cusps, so that the central or occlusal fovea of the molars covers more of the crown surface of the tooth (even so, these features show some variability in *Ramapithecus* and *Dryopithecus* as well as in modern *Homo* and *Pan*); sides of the upper molars, particularly, are more vertical; also differs from *Dryopithecus* in showing a larger and lower canine fossa, an arched palate, arcuate tooth row and a much shorter rostrum."

Although this generic definition of *Ramapithecus* by Simons and Pilbeam is much lengthier than that of Lewis, it cannot be regarded as satisfactory for the following reasons:

(a) It makes size a generic character in that it states "slightly smaller overall size than *Dryopithecus* and *Australopithecus*", but immediately refers to an exception. Moreover, should a larger species of the genus be discovered, it would automatically be excluded by this diagnosis. It must, therefore, be emphasized that size is never really valid as a generic character.

(b) It states that the mandible is "shallower" than in *Australopithecus* and *Dryopithecus*. It does not say whether this is in relation to the overall size, or whether it is shallower only relative to the length of a tooth row. This feature again makes size, for example, "shallower", a generic character, which is taxonomically unsatisfactory.

(c) It goes on to say "shorter face", but because no complete face of *Dryopithecus* (other than in the *Proconsul* group) has been found and certainly no complete face from gnathion to nasion in *Ramapithecus*, this seems to be a most unwise diagnostic character to attribute to the genus, in the present state of our knowledge.

(d) The character "incisors and canines reduced in relation to cheek teeth when compared with *Dryopithecus*" may be valid for Asia but it is not true for specimens from East Africa which Simons and Pilbeam wish to include in *Ramapithecus*. While it may be true in respect of *Ramapithecus punjabicus* (*brevirostis*) (if indeed incisors of this genus and species are known in Asia, of which I am not aware) when compared with the more classical *Dryopithecus* species, it is certainly not true (see below) in respect of comparisons of the incisors as between *Kenyapithecus* and the *Proconsul* group, which Simons and Pilbeam insist on including in the genus. One thing is clear: neither the original East African species *Kenyapithecus wickeri* nor the new species of *Kenyapithecus*, which is to be described below, can be accommodated within the genus *Ramapithecus*, as it is now diagnosed by Simons and Pilbeam. *Kenyapithecus* must, therefore, on their own showing, be retained as a distinct and separate genus.

### Revised Diagnosis

The following new diagnosis for the genus *Kenyapithecus* is now proposed. It is the result of examining not only the original type as well as other more recently recovered additional Fort Ternan specimens, but also the specimens which are now to be placed in a second and geologically rather older species of *Kenyapithecus*, from Songhor and Rusinga.

Hominidae in which the dentition closely resembles that of *Homo* in the broader aspects, but not in the crown structure of the canines, nor that of the upper 3rd premolars. The upper canines have short crowns with compressed and relatively short roots, the crowns are not of the *Homo* type, but more primitive. The upper incisors are shovel-shaped, and closely resemble those of some members of the genus *Homo*. The dental arcade of the maxilla is arcuate, not U-shaped as in the Pongidae, while the alignment of the cheek teeth in the maxillae and also in the mandible diverges posteriorly. The face is only slightly prognathous. There is no diastema in the upper or lower dental series. The premolars and molars, including both upper and lower, either have no cingulum, or else a very reduced one. The lower molar cusps are widely spaced and crowns of the teeth lower relative to crown size than in Pongidae. A true fossa canina is present and is morphologically somewhat of the general type seen in *Homo sapiens*. In this character, *Kenyapithecus* differs very markedly from the Pongidae, but resembles *Ramapithecus*. The cross-section through the symphysis of the mandible resembles that of primitive species of the genus *Homo*, and is quite unlike that to be seen in *Dryopithecus*, *Sivapithecus* or *Proconsul*, or in modern Pongidae.

*Kenyapithecus wickeri*, Leakey

The first species of *Kenyapithecus* to be described is *Kenyapithecus wickeri*, Leakey. It comes from the Upper Miocene deposits of Fort Ternan, Kenya, and was announced in 1961. Since then an additional upper central incisor has been found from the same site and level as the original material. The description and measurements of this incisor are as follows:

Crown width	10 mm
Crown height (labial)	10-25 mm
Crown height (lingual)	10-25 mm
Diameters of root at junction with crown	
Labio-lingual	6.5 mm
Bilateral	7.5 mm

This left upper central incisor of *Kenyapithecus wickeri* from Fort Ternan was recovered after the original type specimen had been described. It was found the following year a few feet further into the cliff at the same horizon. It is very well preserved except for the root, the distal end of which is missing.

This tooth is remarkably like that of *Homo* and differs in a number of characters from the corresponding teeth of *Proconsul* (Fig. 1). Moreover, it has characters in common with the australopithecines, in particular in the cross-section of the root where it meets the crown. In the upper central incisors of *Proconsul*, the root at the junction with the crown is approximately trihedral, and has a greater diameter from the labial to the lingual aspect than from side to side. In the *Kenyapithecus wickeri* specimen, the cross-section is not trihedral but much more oval with the maximum diameter from side to side, while the labial-lingual diameter is reduced. The height of the crown of this tooth, which is practically unworn, is less than the width, and it is more compressed labio-lingually compared with corresponding teeth of *Proconsul*. The region near the cutting edge is very thin providing a fine chisel edge very different from the upper incisors of

*Proconsul*, where a marked medial thickening extends almost to the top of the crown.

The upper central incisors of *Proconsul* are not known for the species *Proconsul major*, but we have well preserved examples of both *Proconsul africanus* and *Proconsul nyanzae*, some of them found in direct association with the rest of the upper dentition, so that identification is certain (see Fig. 1). MacInnes<sup>10</sup> described the upper central incisors of a specimen found in 1932-33 on Rusinga Island. At that time, *Proconsul nyanzae* had not been recognized as distinct, so that he provisionally attributed the specimen to Hopwood's *Proconsul africanus*. Subsequently, Le Gros Clark and Leakey<sup>8</sup> showed that it belonged to the species *Proconsul nyanzae*. These authors accepted MacInnes's description of the incisors as adequate, and did not, therefore, elaborate on them in their own report. MacInnes's description is reproduced here for convenience. It reads as follows:

"The root and base of the crown of the first incisor is roughly trihedral in section, with a flat surface to the front. The apex of the crown is sharply constricted from front to back, the anterior surface being gently convex from above downwards, while the posterior surface is rather sharply concave, producing a flat chisel edge. The median surface shows a pressure facet produced by contact with the first incisor of the opposite side, which lies at right angles to the cutting edge of the tooth, while the outer angle of the cutting edge is more rounded. From each of these two angles a very distinct crest curves downwards and backwards and inwards, the two uniting posteriorly. From the middle front of the posterior surface a massive enamel buttress extends from the base of the crown to a point about half-way to the cutting edge. The enamel is considerably wrinkled, particularly on the posterior surface."

New *Kenyapithecus*

The second and new species of the genus *Kenyapithecus* has, as its Type, the maxilla provisionally described in 1951 by Le Gros Clark and Leakey as *Sivapithecus africanus*.

*Kenyapithecus africanus* (Le Gros Clark and Leakey)

The *africanus* species of the genus *Kenyapithecus* differs from the genotype (*wickeri*) in the following characters: the canine fossae are present, but are less developed; the upper 3rd premolars exhibit two strongly developed and divergent labial roots; their crowns are markedly wider labially than lingually, giving a triangular outline when viewed from the occlusal surface. Traces of anterior internal cinguli are present in the molars and premolars; the upper canines are larger relative to the premolars and molars than in the species *wickeri*. The following additional characters can be seen in the mandible. The corpus in the region of the 4th premolar and 1st molar is deep and very slender, in marked contrast to all Pongidae, including *Proconsul* and *Dryopithecus*; the anterior face of the mandible has a rounded contour, which projects forward in front of the gnathion; the cross-section through the symphysis is markedly hominid in shape, and quite unlike *Proconsul*, *Dryopithecus* or *Sivapithecus*. The available evidence suggests marked sexual dimorphism.

*Type.* The type specimen is CMH 6, Nairobi, from Rusinga site R. 106. 1948. It is in the British Museum (Natural History), London.

This specimen was originally described in some detail, and therefore only a few additional features need to be commented on. In the first place, definite evidence of the presence of a canine fossa can be seen on the maxilla. Second, the root of the malar-maxillary process is set forward over the 1st upper molar as in *Kenyapithecus wickeri* and in *Ramapithecus*, not as in the Pongidae or *Proconsul*. Both these features seem to be characteristic of the early Hominidae and are missing in *Dryopithecus*

and *Proconsul*. The upper 3rd premolar has two pronounced labial roots (Fig. 2).

### Additional Material

The following seven specimens which are in the collections in the Centre for Prehistory and Palaeontology, Nairobi, are now referred to *Kenyapithecus africanus*. (1) Part of the right side of a mandible No. CMH 142 from Rusinga, site 106. (2) Part of a mandible from Rusinga found on the surface in 1948—specimen No. 276. (3) Two incomplete maxillae of a single individual, from Songhor, specimen Nos. Sgr. 52 and Sgr. 111 of 1948. (4) A fragment of a mandible from Songhor, specimen Sgr. 417 of 1951. (5) An incisor from Rusinga, site R.106. (6) An isolated right upper 2nd molar from Songhor, specimen 404 of 1948. (7) A maxilla fragment from Songhor, No. 748 of 1962. (8) A maxilla fragment from Songhor No. 1377 of 1962. (9) Part of a clavicle from Rusinga, site R. 106 of 1947.

#### (1) Mandible fragment, specimen No. CMH 142

Specimen No. CMH 142 comes from the same site (R. 106) as the Type, but was found on the surface nearby. It consists of part of the right corpus of a large mandible which is broken anteriorly in the region of the root of the right lateral incisor, and posteriorly through the roots of the 1st molar. All the crowns of the teeth are missing, but the corpus is well preserved from the alveolar margin to the lower border (Fig. 3).

The mandible fragment was provisionally referred by Le Gros Clark and Leakey to *Proconsul major* on account of the very great depth of the corpus, which measures 39.5 mm in the region of the lower 4th premolar, compared

with 41 mm in the large mandible which is the paratype of the *Proconsul major*. The crowns of the teeth were all missing and, in view of the very scant knowledge of the fauna in 1951, it therefore seemed preferable at that time to refer this specimen to the largest of the *Proconsul* species. The most important differences which can now be clearly distinguished are:

(a) At the level of  $P_4M_1$  the depth of the corpus is only very slightly less than that seen in *Proconsul major*, but the thickness of the mandibular, at this point, is totally different; the corresponding measurements at  $P_4M_1$  are:

<i>Proconsul major</i>	Depth 41 mm	Thickness 22 mm
<i>Kenyapithecus africanus</i>	Depth 39.5 mm	Thickness 12 mm

(b) In the known mandibles of *Proconsul major* there is a clearly defined diastema between the lower 3rd premolar and the lower canine; in this specimen the anterior lingual root of the lower 3rd premolar is set far forward and extends well beyond the posterior rim of the alveolus of the canine, and there is no diastema (Fig. 4).

(c) In *Proconsul major* (as also in both the other species of the genus) the furthest posterior projection of the symphyseal region is set high in the mid-line and extends well back, so that its limit is almost in line with the lower 4th premolar. In this specimen the most backward part of the symphysis is not further back than the level of the front of the 3rd premolar, and may be even further forward.

(d) In *Proconsul major* the inner wall of the corpus, in the region of the premolars, slopes slightly inwards, and the corpus itself is very thick. In this specimen the outer wall is at first straight, then turns slightly outwards.

(e) The area of the root of the canine in *Proconsul major* is marked by a strong surface swelling of the anterior face of the mandible, giving a clear line of demarcation between the "chin" region and the lateral wall of the corpus. In this specimen, there is no such swelling and the root of the canine is much less massive.

(f) The roots of the lower canines are more laterally compressed than in any *Proconsul*, and are orientated more antero-posteriorly and less transversely than in any species of *Proconsul* or Pongid.

(g) The whole mandibular structure is gracile even though the corpus is very deep (39.5 mm).

(h) The mental foramen lies relatively low on the corpus, and is situated beneath the 4th premolar, instead of below the 3rd premolar as in *Proconsul major*.

#### (2) Mandible fragment, specimen No. 276

The second specimen now referred to *Kenyapithecus africanus* is the anterior part of another mandible. It is somewhat weathered and was found on the surface. As such, it was not considered of much importance when the 1951 report was prepared. Its morphology, however, is of such a nature that it now becomes clear that it cannot represent the genus *Proconsul*. It displays a number of features, especially in the cross-section of the symphysis and on the anterior face of the "chin" region, which indicate a remarkably hominid structure (Fig. 3).

Because it clearly does not represent a *Proconsul*, and because it shares so many features in common with other specimens now referred to *Kenyapithecus africanus*, it seems wise to consider this specimen as representing the latter genus and species. This decision is reinforced by the fact that a wholly comparable, but rather smaller, fragment of mandible (see later) has been found at Songhor, close to the point where two maxillae specimens of this same species had been discovered (see following section).

In this second referred specimen, all the crowns of the teeth are missing. The preserved part extends from the anterior edge of the alveolus of the 4th premolar on the right side round to the alveolus of the left 4th premolar. While both the 4th premolars are only represented by

parts of the roots, the lower 3rd premolars, both canines and all four incisors, have their roots intact. There is no trace of a diastema between the lower 3rd premolars and the canines. This is a marked contrast to the conditions to be seen in the various *Proconsul* species. Instead of a diastema, we find that the anterior root of the 3rd premolar is pushed well forward beyond the posterior rim of the alveolus of the canines (see Fig. 4).

The arrangement of the incisors in the alveolus is clearly to be seen along the alveolar margin, and differs very markedly indeed from the crowded condition to be seen in any mandible of any species of *Proconsul*. The four incisor teeth were set more or less in a straight line between the canines instead of with the two central incisors being more forwardly placed (Fig. 4). In this character there is close resemblance both with *Homo* and with *Australopithecus*, but not with *Proconsul* or *Dryopithecus*. The roots are set vertically in the mandible and are not procumbent. The preserved roots of the canines indicate somewhat robust, but not very large, teeth. They are strongly compressed bilaterally, and are placed more antero-posteriorly than in *Proconsul*. Viewed from the front the chin region differs most markedly from that of any species of *Proconsul*, in all of which the anterior region suggests an inverted triangle with the base of the triangle along the alveolar margin of the incisors and the apex of the triangle near the middle point of the lower border of the symphysis. In *Proconsul* there is also a marked backward slope of the anterior face of the mandible in the chin region. In the specimen now referred to *Kenyanthropus africanus* the morphology of the anterior part of the mandible is remarkably like that in a primitive *Homo*, such as the Mauer jaw. The most forward projecting part lies below the alveolus of the central incisors. The whole shape of this region is, moreover, well rounded and filled out (Fig. 3), quite unlike any *Proconsul* or *Dryopithecus*. The cross-section through the symphysis is also different (Fig. 5) and recalls that of the more primitive members of the genus *Homo* and of some australopithecines.

### (3) Incomplete maxillae, specimens

Nos. Sgr. 52 and Sgr. 111

Two parts of a palate became separated before they were embedded in the deposit in which they were found. The fracture of one premolar is, however, subsequent to the specimen having been eroded from the deposits. Specimen No. 52 consists of a part of the right maxilla. It contains both premolars and the 1st

Two parts of a palate became separated before they were embedded in the deposit in which they were found. The fracture of one premolar is, however, subsequent to the specimen having been eroded from the deposits. Specimen No. 52 consists of a part of the right maxilla. It contains both premolars and the 1st

molar. The root of the canine is preserved in the alveolar wall, but the crown has broken off. The specimen has also been broken away some 15 mm above the alveolar margin, in an irregular fracture. In this region, a cross-section of the canine root near the tip is exposed. Above the upper 4th premolar and the upper 1st molar, the maxillary sinus can be seen, filled with matrix. On the palatal aspect the fracture is just short of the palatal suture, which is not preserved. The two cross-sections through the root of the canine (one near the tip and one at the alveolus) reveal that this tooth was orientated in the maxilla with its long axis in much the same direction as that of the molar-premolar series. The labio-lingual width is almost equal to the antero-posterior measurement. At the fracture near the alveolar margin the measurements of the root are 11 mm (antero-posteriorly) and 10.5 mm (bucco-lingually). At the fracture near the tip of the root, about 15 mm above the alveolar margin, the corresponding figures are 8 mm and 6 mm, respectively.

The 3rd premolar has a crown which is roughly triangular in outline when viewed from the occlusal surface—it is very much wider on the labial than on the lingual aspect. The greater labial width is linked with the presence of a very robust anterior labial root and with a rather pronounced anterior cingulum (Figs. 2 and 6). A somewhat similar morphology can be seen in certain specimens from Asia which are classified as *Sivapithecus sivalensis*, and is also present in the Type specimen of *Kenyanthropus africanus*. The single lingual root of the 3rd premolar is very robust and is directed at a wide angle into the palatal area, instead of nearly vertically into the alveolar margin as in *Proconsul*. The two labial roots of this tooth are strongly developed as in the Type specimen of *Kenyanthropus africanus*. The contact area between the crowns of the upper 3rd and 4th premolars is large and flat, as a result of considerable antero-

posterior compression of the teeth, which in turn is correlated with the marked facial shortening. In this character, there is a strong resemblance to the position to be seen in the other and geologically younger species of the genus—*Kenyapithecus wickeri*, from Fort Ternan. The crown area of this upper 3rd premolar is unfortunately rather worn so that the details of the cusp pattern cannot be clearly studied. The measurements of this tooth are: bucco-lingual width 10.25 mm, antero-posterior length 9 mm.

The 4th premolar is narrow antero-posteriorly (both on the lingual and labial aspects) and is wide bucco-lingually. Like the upper 3rd premolar, it has two labial and one lingual root. The labial enamel surface of the crown is very convex antero-posteriorly, and there is no trace whatever of a cingulum. The contact facet of the crown with the upper 1st molar is also large and flat.

The 1st molar, while roughly rectangular in outline viewed from the occlusal surface, is slightly less wide labially than lingually. All four cusps are worn, but the two on the lingual aspect much more so than those on the labial side. No trace of a cingulum is visible. The cusp pattern of this molar is entirely different from that of any species of *Proconsul*. On the labial face of the crown, moreover, there is a clear valley which separates the anterior from the posterior cusp area. This valley extends half-way down the side of the crown.

The second maxilla fragment, *Sgr.* 111, comes from the left side of the same individual. Only the 4th premolar is intact; the 3rd premolar is represented by its roots and by a small portion of the crown. The canine is represented by a broken root which is still in the socket. This root is clearly set in a much more vertical position in the maxilla than in any species of *Proconsul*, or for that matter in any member of the Pongidae. The length of this canine root can be estimated to have been about 24 mm. It has a similar cross-section to that which has been described in the other maxillary specimen.

An interesting feature of *Sgr.* 111 is the presence of a well marked *fossa canina* on the maxillary surface, above the 3rd and 4th premolars. This does not exhibit quite the same depth, or morphology, as in *Kenyapithecus wickeri*, where the position is nearly like that in *Homo*. Nevertheless, it is much more developed and more man-like than in any fossil or living pongid. A trace of a similar canine fossa occurs in the type specimen, but unfortunately the main part of the relevant area is broken away. On this second maxilla fragment the fracture of the palate is at or near the palatal suture and the palate is seen to have been rather flat and shallow.

Table 1

	<i>M</i> <sup>1</sup>		<i>P</i> <sup>4</sup>		<i>P</i> <sup>3</sup>	
	<i>L</i> <sup>*</sup>	<i>B</i> <sup>*</sup>	<i>L</i>	<i>B</i>	<i>L</i>	<i>B</i>
<i>Kenyapithecus africanus</i>	10	11	7.5	10.5	9.5	11.5
<i>Kenyapithecus wickeri</i>	10.5	10.5	6	10.25		
<i>Ramapithecus brevirostris</i> (cast)	9.2	10.9	6.7	10.0	6.9	10.3
<i>Sivapithecus sivalensis</i> (cast)	10.5	11.5	7.0	11.0	9	10.5

All measurements are in mm.

Note. Measurements made on casts may not be very reliable because the degree of accuracy of the cast is unknown.

\* *L*, Antero-posterior length; *B*, bucco-lingual width.

Table 1 sets out the measurements of the teeth of the type of *Kenyapithecus africanus* compared with the type of *Kenyapithecus wickeri*, as well as the type of Lewis's *Ramapithecus brevirostris* and a comparable specimen of *Sivapithecus sivalensis*.

Fig. 5. Comparisons of cross-section of mandibles at symphysis. *a*, *Proconsul major*; *b*, *Proconsul africanus*; *c*, *Proconsul nyanzae*; *d*, *Pan satyrus*; *e*, *Kenyapithecus africanus* (male?); *f*, *Kenyapithecus africanus* (female?); *g*, *Homo habilis*.

#### (4) Mandible fragment, specimen No. *Sgr.* 417

The fourth referred specimen is a mandibular fragment which was found at Songhor near the maxillae described above. It may perhaps represent the same individual. It clearly comes from a mandible that must have been considerably smaller than the first and second referred specimens, and this may, perhaps, be regarded as evidence of sexual dimorphism. It has been noted that the Songhor maxillae fragments found nearby are also somewhat smaller than the type specimen from Rusinga site *R.* 106. This specimen consists of the anterior segment of a mandible of small size, embracing the broken right canine, the roots of all four incisors and the fractured root of the left canine. The canine roots are very small. The whole depth at the symphysis is preserved and the inferior border is intact. One of the most striking characters, and one which clearly places this specimen outside the genera *Proconsul*, *Limnopithecus* and *Dryopithecus*, is the cross-section through the symphyseal region (Fig. 5) together with the shape and fullness of the anterior face of the mandible in the mid-line. In this character the present specimen duplicates what has already been described in the second referred specimen.

The nature of the cross-section through the symphysis of this specimen is very similar to that in the second referred specimen of the *Kenyapithecus africanus* mandible. The roots of the canines and of the incisors are placed nearly vertically in the corpus, and the incisor roots are noticeably less crowded together than in a *Proconsul* of comparable size.

#### (5) Upper central incisor, specimen No. *CMH* 9

In 1951 Le Gros Clark and Leakey figured an upper central incisor from Rusinga Island as a possible incisor of *Proconsul nyanzae*, but more detailed study shows that it does not agree in its overall morphology with specimens which can be shown to belong to *Proconsul*. On the other hand, it agrees remarkably, in structure, with the upper central incisor of *Kenyapithecus wickeri* (see Fig. 2). It is slightly less like a shovel-shaped incisor of the genus *Homo* than the corresponding tooth of *Kenyapithecus*

*wickeri*, but we have already seen that in other characters also *Kenyapithecus africanus* is somewhat less evolved in the hominid direction than the geologically younger species *wickeri* from Fort Ternan. The tooth is large, with a maximum crown diameter of 10 mm and a labial-lingual diameter at the base of the crown of 7.25 mm. It exhibits only a small degree of wear on the crown, and the dentine is not exposed. The lingual surface of the crown is rather concave in longitudinal section and slightly so in transverse section. The cutting edge is straight, and on the median side the lateral edge is almost at right angles at first, and then curves inwards to the neck. The lateral edge, in contrast to the median edge, descends in a smooth curve outwards before turning inwards to the neck of the tooth, at the commencement of the root. In these characters the crown parallels the upper central incisor of *Kenyapithecus wickeri* to a remarkable degree (Fig. 1). The root is rather less compressed labio-lingually than in *Kenyapithecus wickeri* and is more nearly trihedral. In this single respect it resembles the roots of *Proconsul* incisors but the labial face of the root, near the neck, is slightly convex from side to side. The measurements of the root at the neck are labio-lingual width 7 mm, bilateral width 7 mm.

The morphology of the lingual aspect of the crown is perhaps the most interesting character, and here the resemblance is wholly with *Kenyapithecus wickeri*, and not at all with *Proconsul nyanzae* or *africanus*. The typical structure of the labial aspect of the upper central incisors of *Proconsul* as described by MacInnes<sup>10</sup> has already been quoted.

There are now six additional *Proconsul nyanzae* upper central incisors available for study in the Nairobi collection. Although they show minor points of variation, they all conform to the same morphological pattern, which has at its most marked feature a convex buttress running centrally from the base of the crown almost to the tip on the lingual face.

**(6) Upper right second molar, specimen No. 404** Closely resembling the 1st upper molar of specimen *Sgr.* 52 is an upper right second molar from Songhor. Nevertheless the condition of wear on the occlusal surface and examination of the contact facets on either side indicate that it belongs to another individual. It is probably female. The measurements of this tooth are bucco-lingual diameter 11.5 mm, antero-posterior diameter 10 mm.

**(7) Maxilla fragment, specimen No. 748** This maxilla fragment is from the right side. It contains the 3rd and 4th upper premolars, which are beautifully preserved and only very slightly worn. As in the other specimens of *Kenyapithecus africanus*, the width of the 3rd premolar is much greater on the labial than on the lingual aspect so that the tooth viewed from the occlusal aspect is slightly triangular in outline. There are two labial roots to this tooth and, as in the type specimen from Rusinga site *R.* 106, the anterior one is very massive. The contact with the 4th premolar is large and flat. The 4th premolar is wide bucco-lingually and narrow antero-posteriorly, the respective measurements being 11.5 mm and 7 mm. In size and morphology these two teeth conform closely with the corresponding teeth in the type specimen and probably represent a male.

**(8) Maxilla fragment, specimen No. 1377** The maxilla fragment No. 1377 from Songhor is from the left side and, like No. 7, also contains only the two premolars. It is distinctly smaller than No. 7 and the teeth are comparable in size, as well as in morphology, with the corresponding two teeth in *Sgr.* 52 of 1948 (see section 3). It is presumed to be female.

The measurements of these two teeth are as follows:

*P*<sup>3</sup>—Antero-posterior length 8.5 mm; bucco-lingual width 10 mm.  
*P*<sup>4</sup>—Antero-posterior length 6 mm; bucco-lingual width 10 mm.

Besides the specimens listed, which certainly represent *Kenyapithecus africanus*, there are some eight other specimens which, possibly, should also be referred to this genus and species, but the evidence is less certain. When more complete material has been discovered it may be possible to diagnose these specimens further.

**(9) Part of a clavicle, specimen No. 604, 1947**

Le Gros Clark and Leakey<sup>9</sup> briefly noted a part of a clavicle from Rusinga site *R.* 106, No. 604. It was found close to the type specimen and to specimens 1–5 here, and may belong to the same individual.

### *Kenyapithecus*, species indet.

In 1951 Le Gros Clark and Leakey provisionally referred an upper first molar found on Maboko Island to what they then called *Sivapithecus africanus*. The question therefore arises as to whether this specimen represents the genus *Kenyapithecus* and, if so, which species.

The deposits at Maboko Island are no longer regarded to be of the same age as those of Rusinga, Songhor and Koru. They are usually now either referred to the uppermost Miocene, or to the early Pliocene, and are considered to be of roughly the same age as those of the Fort Ternan site.

The molar tooth in question conforms in all respects to molars of *Kenyapithecus* and must certainly be regarded as representing that genus. For the moment it seems better not to assign it to any particular species. It was illustrated in Plate VI, Fig. 44, of Le Gros Clark and Leakey.

During the current study an upper left central incisor from Maboko Island (Fig. 1) was discovered. It clearly also represents the genus *Kenyapithecus* and is also, for the moment, treated as species indet. The measurements of this incisor tooth *MB.* 142 (*CMH* 11) are as follows: labio-lingual width at base of crown 7.25 mm; transverse diameter of crown 9.75 mm; anterior height of crown 11.00 mm; internal height 11.5 mm.

## Discussion

### Status of *Kenyapithecus africanus*

Although in 1963 Simons supported the view that what Le Gros Clark and Leakey called *Sivapithecus africanus* would prove to stand very close to *Kenyapithecus wickeri*, he abandoned that idea in 1965. He and Pilbeam have now jointly suggested that specimens which they group together as the "Sivapithecus" group of Primates are no more than a sub-genus of *Dryopithecus*. They suggest that there are two distinct species of this "sub-genus"; one *Sivapithecus indicus* and the other *Sivapithecus sivalensis*.

I consider that it would be much wiser to retain the generic name *Sivapithecus* for the truly Asiatic members of Dryopithecinae, reserving the generic name *Dryopithecus* for the European forms belonging to this sub-family. This is purely a matter of definition and it is never easy to decide just what should constitute a genus or what a sub-genus. It is, however, important to bear in mind that the differences between *Sivapithecus indicus* and *Sivapithecus sivalensis* appear to be marked, and that what is known as *Sivapithecus sivalensis* is possibly not a *Sivapithecus* at all. There seems to be no doubt that the species *Sivapithecus sivalensis* in India may stand much closer to the genus *Ramapithecus* than it does either to *Sivapithecus indicus* or to the true European *Dryopithecus* specimens.

or even to the East African *Proconsul* stock. This can be clearly established by examining the morphology of the molar and premolar teeth.

Simons and Pilbeam have expressed their opinion that the specimen which Le Gros Clark and Leakey originally called *Sivapithecus africanus* is indistinguishable "both generically and specifically" from the Asiatic *Sivapithecus sivalensis*. They also maintain that *Kenya-pithecus wickeri* is identical with *Ramapithecus punjabicus*. In the light of the foregoing study, I strongly reject both these opinions as having no adequate foundation in the light of the data which are now available. The following are two of the principal reasons for the rejection of Simons and Pilbeam's views on this matter:

(a) The diagnosis of *Ramapithecus* which has been given by Simons and Pilbeam states that, in the genus *Ramapithecus*, the mandible is "shallower" than in *Dryopithecus* and *Australopithecus*. This is certainly not true of *Kenya-pithecus africanus*, where we have a mandibular fragment which is 39.5 mm deep at the level of the 4th premolar.

(b) They further state that the incisors and canines are "reduced in relation to the cheek teeth when compared with those of *Dryopithecus*". I do not know what incisor teeth of the Asiatic *Ramapithecus* they have examined as a basis for this statement, but it is emphatically not the case when the size of the upper central incisor of *Kenya-pithecus wickeri* or of *Kenya-pithecus africanus* is compared with the premolars and molars of the same individual.

Table 2

	Upper central incisors		Upper 4th premolars		Upper 1st molars	
	Crown bilateral width	Bucco-lingual width at base of crown	Antero-posterior diameter	Bucco-lingual width	Antero-posterior diameter	Bucco-lingual width
<i>K. wickeri</i>	10	6.5	6	10.25	10.5	10.5
<i>K. africanus</i>	10	7.5	7.5	11.5	10.6	11.3
<i>P. nyanzae</i>	7	8.0	7.0	10.5	10	11.0
<i>P. africanus</i>	6	6.4	7.5	9.7	7.9	9.6

The corresponding modules comparing central incisors with 4th premolars are 8.25-8.125 and 8.625-9.65 in *Kenya-pithecus* and 7.5-8.75 and 6.2-8.6 in the *Proconsuls*. Similarly the modules comparing measurements of the first molars are 8.25-10.5 and 8.625-10.9 in *Kenya-pithecus* and 7.5-10.5 and 6.2-8.75 in the *Proconsuls*.

Table 2 sets out the relative measurements of the upper central incisors, upper 4th premolars and upper 1st molars (in each case in a single individual) from specimens representing *Kenya-pithecus wickeri* and *Kenya-pithecus africanus* (Hominidae) and *Proconsul nyanzae* and *Proconsul africanus*. Reference to the upper 3rd premolars is omitted because we do not have this tooth in *Kenya-pithecus wickeri*. Table 2 shows that in *Kenya-pithecus* the upper central incisors are not reduced relative to premolars and molars, but are large relative to them when compared with the *Proconsul* group.

While it is readily agreed that *Ramapithecus* should be regarded as a member of the Hominidae—an Asiatic member—the new evidence suggests that it should not—at least at present—be treated as identical to *Kenya-pithecus*. Good specimens of the symphyseal region of the mandible of *Ramapithecus* are required, as well as information about its upper incisors, before we can be certain.

It has been proposed in this article that the former "*Sivapithecus africanus*" should now be regarded as a Lower Miocene representative of the genus *Kenya-pithecus*, and called *Kenya-pithecus africanus*, because it clearly stands close to *Kenya-pithecus wickeri*. It has among other things (a) an incipient *fossa canina* of *Homo* type, (b) a very thin mandibular ramus relative to depth, (c) no diastema in the lower dental series, (d) transverse section through the symphysis of hominid type, and (e) an upper central incisor of hominid structure. Until *Sivapithecus sivalensis* can be shown to share all these features, identity cannot be accepted.

Fig. 6. Comparison of upper dentition from occlusal view. a, *Ramapithecus brevivostis* (cast); b, *Proconsul africanus*; c, *Sivapithecus sivalensis* (cast); d and e, *Kenya-pithecus africanus*; f, *Kenya-pithecus wickeri*.

## Geological Age

The geological age of the Rusinga deposits and also of those at Songhor is usually regarded as Lower Miocene. The fauna of even the youngest part of the series is regarded as at least two "faunal stages" older than the fauna of Fort Ternan<sup>11</sup>, which is considered to be Upper Miocene. The Fort Ternan fauna includes primitive Bovidae with well developed horn cores, while even in the youngest deposits of Rusinga and Songhor there are no true Bovidae with horns. Ungulates are represented, instead, by several hornless members of the Tragulidae.

While dealing with the question of age, it is necessary to consider briefly certain suggestions that have been made that the fauna of Rusinga, Songhor and Koru, etc., ought not to be regarded as of Lower Miocene age, but as somewhat younger. The most serious argument which has been advanced against a Lower Miocene age for the Rusinga formation has come from Evernden, Curtis and Savage, and this must, therefore, be critically examined. They have, in effect, expressed the view that an age of about  $15 \times 10^6$  yr, which was obtained by the potassium-argon method of dating on a specimen collected in the R. 106 region of Rusinga, near the foot of the Kiahera Hill, should be regarded as the date for the whole Rusinga series. Kiahera Hill consists mainly of rocks which belong to Shackleton's "Kiahera Series"<sup>12</sup> which he believes to represent the oldest part of the Rusinga sequence. Curtis and Evernden's sample certainly came from "near the foot of Kiahera Hill" and it has been assumed that it must, therefore, belong to a low level in the Kiahera series.

This is not necessarily the case. There are a number of faults and unconformities in the area, and the Kathwanga series, which Shackleton regarded as possibly the youngest part of the Rusinga rock sequence, rests against Kiahera Hill in several places. The sample that was used to obtain a potassium-argon age of about  $15 \times 10^6$  yr may perhaps have come from the Kathwanga series.

Of greater significance than this single potassium-argon figure, for the purpose of accurate dating, is the fact that the fauna of even the youngest part of the Rusinga Miocene series (as already stated) differs markedly from the Upper Miocene fauna of Fort Ternan. It differs, in fact, by at least two "faunal stages". If the Fort Ternan deposits are correctly dated by potassium-argon dating, as about  $14 \times 10^6$  yr, then the age of  $15 \times 10^6$  yr given for the deposits at Rusinga, near to the base of Kiahera Hill, must be wrong. The possibility cannot, however, be wholly excluded that the uppermost part of the Rusinga sequence, the Kathwanga series, may be of Middle Miocene age, but even this seems to me somewhat unlikely, on the basis of the faunal evidence.

The real question, for the purpose of this present article, is not only the question of the age of the Rusinga Island deposits but also those at Songhor, whence some of the specimens now referred to *Kenyanthropus africanus* have come. At the present time the Songhor deposits are usually regarded to be of the same general age as the main Rusinga series. It must, however, be noted that there are distinct differences in the faunal assemblages between those from Songhor and those from Rusinga. These differences have usually been explained by suggesting that the two sites represent different ecological settings, rather than that they are due to a real difference in geological age because there are certain well defined faunal elements in common. It is, however, possible that the Songhor beds may only represent the upper part of the Rusinga series, and that both may be of Middle Miocene age, leaving the main Rusinga deposits in the Lower Miocene.

Another reason which has been put forward in support of a later age for the Rusinga formation was that advanced by Savage in 1964. The argument runs as follows: *Pliohiprax*, *Mesopithecus*, *Sivapithecus*, together with members of the Tenrecidae, occur in the faunal assemblage from Rusinga and these prove that the age is younger than Lower Miocene, because they are creatures which occur in Middle and Upper Miocene beds elsewhere. This view overlooked the following points:

(1) The identification of *Pliohiprax* has been shown by Whitworth<sup>13</sup> to have been incorrect and the material formerly referred to under that name is, in reality, a *Megalohyrax*.

(2) The specimen which MacInnes very tentatively identified in 1943 as "*Mesopithecus*" was a mandible which came from the site on Maboko Island, and not from Rusinga. This site has since been shown by Simpson to be younger than the Rusinga series, and is probably of Pliocene age. In any event the specimen is not a "*Mesopithecus*". This specimen, therefore, has no bearing whatever on the age of the Rusinga deposits.

(3) The specimen which Le Gros Clark and Leakey called "*Sivapithecus*" was only very tentatively placed in that genus, and it has now been shown not to be a *Sivapithecus*.

(4) The presence of Tenrecidae supports rather than contradicts a Lower Miocene age, because this family no longer exists on the African mainland but only on Madagascar Island, which was cut off from Africa during Lower Miocene times, or even earlier.

While the available evidence suggests, therefore, that *Kenyanthropus africanus* carries the Hominidae back to the Lower Miocene, the possibility that it might be of Middle Miocene age cannot be wholly ruled out, but it is emphatically not of Upper Miocene age. It is, therefore,

distinctly older than *Ramapithecus* and *Kenyanthropus wickeri*, and is the oldest member of the family Hominidae known at the present time.

One of the results of the discovery of remains of a genus of the Hominidae, *Kenyanthropus africanus*, at Songhor and on Rusinga Island, is that it is no longer possible to treat certain of the post-cranial skeletal material which was formerly attributed to *Proconsul* as necessarily belonging to that genus. As Le Gros Clark and Leakey observed on p. 87 of their 1951 report: "A few isolated limb bones attributable to some of the large Hominidae have come to light. Although they are from sites which have also yielded teeth and jaws of *Proconsul*, none of those to be described in this section was found in such close association with those other remains as to permit any assurance that it belonged to the same individual."

The talus and calcaneum (CMH 145 and 146) from Songhor and a very similar talus from Rusinga (CMH 147) were assumed to belong to *Proconsul* and referred provisionally to the species *nyanzae* (on account of their size), but it was recognized in 1951, and must be again emphasized here, that these specimens could just as well belong to some other primate.

The incomplete femora and the shaft of the humerus from the Maboko Island site were also assumed to belong to *Proconsul*, but we now know that the Maboko deposits are younger than the main Rusinga series, and are probably of an Upper Miocene or Early Pliocene age. While *Proconsul* (species indet.) is known to persist as late as the Upper Miocene in East Africa (compare with Fort Ternan and Maboko), it is also clear that at least one incisor tooth of *Kenyanthropus* has been recorded from the Maboko beds, while a primate related to *Oreopithecus* is also present at both sites.

A tibia fragment from Rusinga was also described by Le Gros Clark in 1952 (ref. 14). This, too, can no longer be regarded as necessarily representing the genus *Proconsul*.

Two incomplete clavicles were reported by Le Gros Clark and Leakey; one of them was from Maboko Island, the other was found on Rusinga at site R. 106, which is the site also yielding the mandible fragment and the type maxilla fragment of *Kenyanthropus africanus*, and an incisor of this species. Of these two clavicle fragments, the specimen from site R. 106 is particularly interesting, in view of its close association with material representing *Kenyanthropus africanus*. It has been provisionally referred to that genus. It will be sent to a specialist for study and report.

The work on Rusinga Island and at Songhor was carried out with the aid of grants from the Royal Society (1948), the Boise Fund, and the Wenner-Gren Foundation, while the Fort Ternan site was studied under the auspices of the National Geographic Society. The help of all these bodies is gratefully acknowledged.

## LETTERS TO THE EDITOR

## ASTRONOMY

## Relation between Optical and Radio Properties of Quasars

THE purpose of this communication is to point out some interesting relationships between  $U$ ,  $B$ ,  $V$  colours of quasars<sup>1,2</sup> and their radio polarization properties<sup>3-6</sup>.

Fig. 1. Percentage polarization at 21 cm wavelength for quasars with measured  $U-B$  and  $B-V$ .

In Fig. 1 the percentage polarization at 21 cm wavelength has been indicated on a  $U-B$  against  $B-V$  plot for the quasars for which all three parameters are known. There is a remarkable division: zero polarization in the lower right-hand corner and the higher polarizations in the upper left-hand corner. Values of zero percentage polarization have been allocated to those sources the polarizations of which were less than 1.0 per cent and the quoted errors of which were of the same order as the polarization. Fig. 2 shows a plot of radio rotation measured against the ratio  $U-B/B-V$ . Again a significant relationship is apparent, although further experimental points are needed, such as would be provided by an extension of polarization measurements to lower radio frequencies and weaker sources.

If the  $U$ ,  $B$ ,  $V$  colours are intrinsic source properties, then the relationship between these and the polarization properties is significant. In particular, Fig. 2 indicates that a considerable part of the rotation measures may well be intrinsic to the sources and hence these cannot be used to make any precise models of the galactic magnetic field<sup>4,5</sup>.

Selection effects may be important in such a small sample of data. It is possible, for example, that objects with large  $z$  are only observed if they have a large intrinsic luminosity, which might itself be related both with colour and with radio polarization properties. On the other hand, there is no apparent dependence of the radio polarization properties on  $z$ . Such correlations are harder to explain if the colour or the polarization is determined

Fig. 2. Radio rotation measure versus  $U-B/B-V$  for all quasars for which these parameters are known to date.

by the interstellar medium, but further observations might exclude this possibility. In the case of 3C 138 ( $b'' = -11^\circ$ ), Sandage<sup>1</sup> has corrected the colours for interstellar reddening, but the corrections are uncertain and the source has not been included in the data.

With these reservations in mind, the following comments may be made on the two diagrams. Fig. 1 shows that the objects that are most highly polarized are those with relatively large ultra-violet excess, while the redder objects are unpolarized at 20 cm. Fig. 2 shows that the redder objects also have the largest rotation measures. This could be an evolutionary effect. Initially, the source consists mainly of synchrotron electrons emitting polarized radiation, and as it evolves an increasing number of these electrons decay to thermal velocities, producing an increase in the observed rotation measures. The associated decrease in polarization could be due to differential Faraday rotation, combined with a possible increase in the tangled nature of the magnetic field structure within the source. When a significant fraction of the synchrotron electrons has been thermalized the effect on the spectrum of the source might be detectable.

If we do conclude that the polarization properties are intrinsic to the sources, then the rotation measures should be multiplied by  $(1+z)^2$  before we can compare them closely with other source properties. Extension of polarization measurements to lower frequencies would enable red-shift corrections to be applied to the observed degrees of polarization, so that Fig. 1 could be redrawn showing the intrinsic source polarization at 21 cm, rather than the observed values.

Observations of  $U$ ,  $B$ ,  $V$  colours of radio galaxies would clearly be valuable for comparison with the radio polarization data in the same way.

## PLANETARY SCIENCE

**B and C "Sources" of Jovian Decametric Radiation**

A STUDY has been described of very short duration (less than 50 msec) pulses observed in the decametre-wave radiation from Jupiter<sup>1</sup>. For the period of the observations (November 21, 1965–March 17, 1966) it seemed that this type of radiation was associated with the subsidiary *B* and *C* "sources"<sup>2</sup> on Jupiter rather than with the main source *A*. It is the purpose of this communication to point out a similar tendency in certain polarization observations as well as in the lower frequency observations of Jupiter.

During the 1965–66 apparition a detailed investigation was made at the Florida State University Radio Observatory of the polarization of the radiation from Jupiter. These observations have been reported briefly<sup>3</sup> and a more detailed account will be published later. Left- and right-hand components were compared at 16, 18 and 22 Mc/s using very short time constants and several different chart-speeds as a part of the millisecond pulse experiment already mentioned. The polarization was observed as one of several criteria for establishing that the short pulses did indeed originate from Jupiter.

During the course of the apparition a more elaborate study was also developed at 18 Mc/s. Based on the system described by Cohen<sup>4</sup>, a polarimeter was constructed which measures left- and right-hand components and also the phase and correlation between these components so that all the polarization parameters can be determined. Some correlation measurements previously made by Sherrill<sup>5</sup>, using a longer time constant system, indicated a fairly high degree of polarization, usually greater than 80 per cent. This is confirmed in general for the events analysed so far, although fairly rapid variations sometimes occur

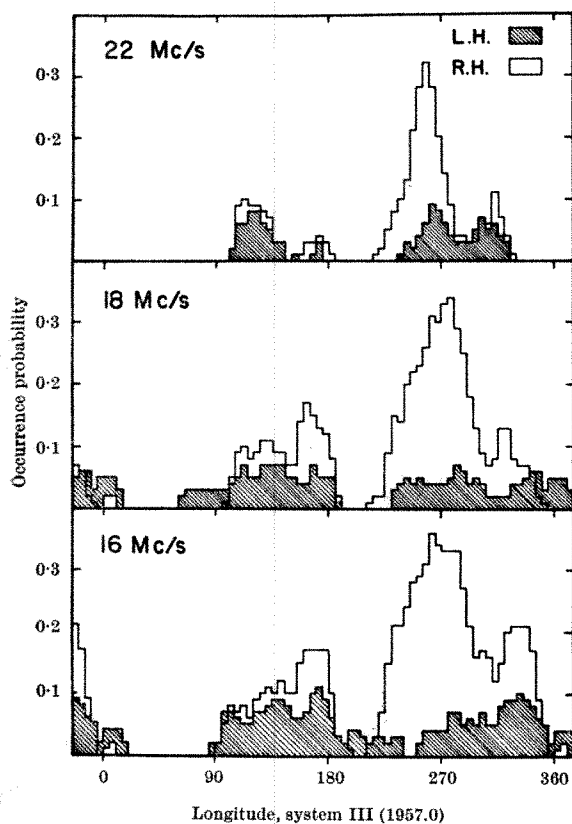

Fig. 1. Histograms of left- and right-hand polarized Jupiter activity, November 1965–March 1966.

Fig. 2. Comparison of different observations in which the main source *A* histogram peak is absent.

which would not have been detectable with Sherrill's polarimeter. While it is unlikely that a detailed analysis of all the observations will be completed for some time, the general trend of the polarization studies can be seen from histograms of periods of predominantly left- and right-handed activity at each frequency.

These histograms are shown in Fig. 1. It can be seen that, as in previous investigations, right-handed polarization predominates at all frequencies, while the incidence of left-handed polarization increases somewhat towards the lower frequencies. In Fig. 2, the histogram of left-handed polarized activity at 16 Mc/s is compared with the histogram of millisecond pulses observed during the same period<sup>1</sup>. The profile of relative power obtained by McCulloch and Ellis<sup>6</sup> at very low frequency is shown in the same diagram. It can be seen that there is a general similarity in the longitude profiles for the millisecond pulse events, the left-handed polarized events and the relative power at 4.7 Mc/s. In particular, the main source *A* peak is not present, while the *B* and *C* sources peaks and the *D* null region are as well defined as in most general observations. Similar tendencies have been found to some extent in earlier investigations by other workers. Dowden<sup>7</sup>, for example, found that the source *A* peak was absent from left-handed polarized bursts observed at 10.1 Mc/s in 1962. Sherrill and Castles<sup>8</sup> and Barrow<sup>9</sup> found some evidence of a left-handed peak corresponding to source *C* at 17.2 and 16 Mc/s in 1962 and 1963.

In the present series of observations, although the millisecond pulses all showed a definite polarization, there did not appear to be any systematic tendency for either left-handed or right-handed pulses to predominate. In other words, the millisecond-type pulses and the left-handed polarization may be independent characteristics of the *B* and *C* sources.

### Crater Diameter-Depth Relationship from Ranger Lunar Photographs

IN 1965, Baldwin<sup>1</sup> investigated the relationship between diameter and depths for some lunar craters from *Ranger VII* photographs. He used the values from the *Ranger Lunar Charts* (RLC) published by the Aeronautical Chart and Information Center. Baldwin found that the diameter-depth relationship for these craters may be represented by the equation

$$D = 0.0256d^2 + d + 0.6300 \quad (1)$$

where  $D$  and  $d$  are the logarithmic diameter and depth of craters in feet.

Recently, I measured the cross sections of some primary craters from the *Ranger VII*, *VIII* and *IX* photographs<sup>2</sup>. Fig. 1 shows the measured values of logarithmic diameter ( $D$ ) and depth ( $d$ ) in metres. There is no difference between the diameter-depth relationship for craters, photographed by the three different *Ranger* missiles

Fig. 1. Logarithmic diameter  $D$  versus logarithmic depth  $d$  (both in m) from *Ranger VII* (○), *Ranger VIII* (×) and *Ranger IX* (●) photographs.

in different lunar regions. The crater diameter-depth relationship, shown in Fig. 1, may be represented by the equation

$$D = 0.96d + 0.98 \quad (2)$$

where  $D$  and  $d$  are the logarithmic diameter and depth of craters in meters. The relationship between  $D$  and  $d$  is practically linear for craters, diameters of which are between 29 and 17,100 m. This fact shows that the well known Ebert's rule is not valid for small lunar craters.

The results obtained are not a contradiction of the meteoritic-impact theory of the origin of lunar craters and it seems that most of the small craters are of meteoritic origin. I thank Professor H. Haffner, director of the Hamburg Observatory, for the hospitality of this institution and for many informative discussions.

### Kamacite-Taenite Relationships in Iron Meteorites

A NUMBER of investigators<sup>1-3</sup> have used the method of electron probe X-ray microanalysis in the examination of metallic meteorites. For those simple octahedrites which are free of visible thermal metamorphism there is general agreement that the various morphological forms of taenite are distinctly non-homogeneous with respect to nickel, whereas the bulk of the kamacite is of more uniform nickel content, although there is a decrease of nickel within the kamacite where it comes into contact with taenite<sup>1,3</sup>. Extensive measurements of this effect have been made by Agrell, Long and Ogilvie<sup>3</sup> on a sample of the Canyon Diablo meteorite, for which they found a nickel content of  $6.8 \pm 0.2$  per cent for the bulk kamacite as compared with about 5.7 at the interface. In the machine used by Agrell, Long and Ogilvie the X-rays could be collected in a direction lying in the plane which contained the normal to the specimen surface and the intersection of the kamacite-taenite boundary with the surface. This simple geometry minimizes the anomalous effects which can arise if X-rays generated in one phase are absorbed by passage through another phase.

In the present work an A.E.I. SEM2 microprobe analyser was used. This is a fully focusing machine of different geometry from that used by Agrell. The meteorite specimens were cut in such a way that the kamacite-taenite interfaces under examination were perpendicular to the surface of the specimen; the traverse of the probe was perpendicular to the interface and also coincided with the Rowland circle of the spectrometer.

Some specimens of the Canyon Diablo meteorite contain crystals of the carbide phase, cohenite, whereas other specimens are free of cohenite and it is not clear which type of material was examined by Agrell. In the present work samples of both cohenite free (CF) and cohenite rich (CR) Canyon Diablo material were examined. In addition, samples of artificially shock hardened CF material were available at 138 and 228 kbar shock wave pressures respectively. Both samples showed the acicular kamacite structure which is characteristic of cosmically shock hardened meteorites and both samples were subject to microprobe examination. Finally, samples of the cosmically shock hardened meteorite Trenton were examined. In all cases the microprobe examination was conducted on unetched specimens after a detailed metallographic

Table 1

Meteorite	Matrix bulk (per cent nickel content)	Kamacite- taenite inter- face (per cent nickel)	Taenite width ( $\mu$ )	Maximum per cent nickel at taenite interface
1 Canyon Diablo CR	6.8 ± 0.1	6.1 ± 0.2	28	42 ± 1
2 Canyon Diablo CR	6.7 ± 0.1	5.7 ± 0.1	34	42 ± 1
3 Canyon Diablo CF	6.9 ± 0.1	5.8 ± 0.2	32	38 ± 1
4 Canyon Diablo CF	6.8 ± 0.2	6.0 ± 0.2	43	42 ± 1
5 Canyon Diablo CF	6.8 ± 0.2	6.1 ± 0.2	Plessite	43 ± 1
6 138 kbar CF	6.8 ± 0.1	6.1 ± 0.2	34	40 ± 1
7 228 kbar CF	6.7 ± 0.1	5.9 ± 0.1	34	40 ± 1
8 228 kbar CF	7.0 ± 0.1	6.1 ± 0.2	50	44 ± 2
Overall mean	6.81	5.97		
9 Trenton	7.4 ± 0.1	6.9 ± 0.1	Plessite	32 ± 3
10 Trenton	7.3 ± 0.1	7.0 ± 0.1	Plessite	35 ± 1
11 Trenton	7.5 ± 0.1	7.0 ± 0.1	Plessite	34 ± 2
Overall mean	7.4	7.0		

examination of the etched specimen outside the microprobe analyser. The results are laid out in Table 1, from which it appears that there is satisfactory agreement between the present measurements on Canyon Diablo meteorite and the results previously obtained by Agrell, Long and Ogilvie using a different machine.

In Table 1 measurements 1-4 and 6-8 relate to bands of taenite, and the tabulated values are the means of values measured on either side of the bands. Measurement 5 relates to the interface between massive kamacite and the outer, nickel rich, taenite which surrounds a plessite region. The metallographic evidence suggests that all such interfaces form under the same conditions and this is supported by the similarity of interface nickel values. All measurements on Trenton were made on the outer rims of plessite areas.

It appears from Table 1 that the conditions at the kamacite-taenite interfaces are identical for both cohenite free and cohenite rich samples of Canyon Diablo. This suggests that both types of material formed under similar conditions and are, in fact, portions of the same large body.

The kamacite-taenite interface relationship is not altered by artificially induced shock wave transformation, at least up to shock pressures of 228 kbar, and it can be presumed that interface composition relationships are similarly undisturbed by the intervention of cosmically induced shock transformation in this pressure range. The kamacite of Trenton has a microhardness (249) similar to that of Canyon Diablo after 228 kbar shock (245) and has a very similar microstructure; thus the interface relationships obtained for Canyon Diablo can be compared directly with those obtained for the cosmically shock hardened material of the Trenton meteorite.

We thank Dr. I. C. Skidmore for the shock hardening of Canyon Diablo meteorite samples.

### Trace Element Content of Antarctic Lakes

THE Taylor and Wright Valleys, McMurdo Sound, Antarctica, contain a series of lakes of particular geochemical interest. Several of these, including Lakes Bonney, Joyce, Fryxell and Hoare in the Taylor Valley and Lake Vanda in the Wright Valley, are, although ice covered, not completely frozen. They are also saline and strongly density stratified, with the waters at the bottom of the lakes containing large amounts of dissolved solids<sup>1-7</sup>. A recent survey of the concentrations of a number of trace elements in the water of the above lakes has been undertaken with the intention of elucidating the origin of the salts present in them<sup>8</sup>. This has shown that it is possible that Lake Bonney has had a sea water origin and

that Lake Fryxell may also have contained some sea water in the past, but that it is unlikely that the other lakes considered here were of marine origin.

Neglecting a sea water origin for the lakes, the salts present could have come from three possible sources:

(1) *Atmospheric recirculation*. It is well known that rain water at considerable distances from the sea contains appreciable quantities of several inorganic ions<sup>9</sup> and it is possible that the salts in the lakes are in part obtained from melted snow. Salts from blown sea spray have also been suggested as contributing to the dissolved material in Lake Fryxell<sup>2</sup>.

(2) *Thermal springs*. These have been suggested as the source of heat in Lakes Vanda, Bonney and Fryxell<sup>3,10</sup> but the evidence is not conclusive<sup>5,6,11</sup>.

(3) *The surrounding rocks*. The Antarctic environment causes widespread alteration of rocks and minerals converting those which are normally stable into readily soluble forms<sup>12</sup>. Elements which are thereby released can be collected into lakes and pools if periodic flushing of the soil occurs, as in the annual thaw. Melt waters of glaciers have been shown to contain small amounts of dissolved rocks<sup>13</sup>. Since all these lakes are fed by the melt waters of glaciers, it is reasonable to expect that elements extracted from the rocks by the glaciers and contained in the melt waters would contribute to the salts in the lakes.

Assuming that the last source is the most probable origin of the elements present in the lakes (there is no definite proof for the existence of thermal springs and the contribution from atmospheric precipitation should be negligible), the relative concentrations of trace elements in the lakes with a probable non-marine origin should provide an indication of possible regions of mineralization in the area.

It has been shown<sup>14,15</sup> that about 1,000 yr ago Lake Vanda had lost most of its water by evaporation (the lake has no outflow), after which the climate changed and fresh water flowed in on top of the strong salt solution and since then the salts have been diffusing upwards. A similar mechanism is proposed for the formation of density gradients in the other lakes. The ions present in the bottom waters are therefore much more concentrated than they were in the original water entering the lakes.

Provided there has been no precipitation of dissolved material during the period in which the lakes are assumed to have evaporated to low bulk, the ratio of trace element concentration to that of total dissolved solids in the lakes now will be the same as in the water originally present in the lakes. If this water was originally supplied by glacial-melt and other surface waters only, any anomalously high relative concentrations of trace elements in the lakes should provide a guide to mineralization in the area.

Table 1. CONCENTRATION OF CERTAIN ELEMENTS IN THE BOTTOM WATERS OF LAKES OF MCMURDO OASIS, ANTARCTICA (DATA FOR RIVER WATER INCLUDED FOR COMPARISON)

Lakes	Concentration ( $\mu\text{g/l.}$ )					
	Zinc	Lead	Bismuth	Iron	Manganese	Molybdenum
Vanda	5,400	< 30	6.1	490	44	2.1

Table 2. RATIO OF THE CONCENTRATION OF CERTAIN ELEMENTS TO THE CONCENTRATION OF TOTAL DISSOLVED SOLIDS IN THE BOTTOM WATERS OF LAKES OF MCMURDO OASIS, ANTARCTICA

Lakes	Ratio ( $\times 10^3$ )					
	Zinc	Lead	Bismuth	Iron	Manganese	Molybdenum
Vanda	31	< 0.18	0.035	2.8	0.25	0.011
Bonney	0.38	< 0.077	0.018	1.6	0.059	0.022
Fryxell	2.9	4.3	< 0.21	1.4	0.80	0.024
Joyce	7.6	68	0.76	100	5.4	1.4
Hoare (East Lobe)	31	83	< 2	130	11	1.0
Hoare (West Lobe)	18	83	< 2	450	17	2.6

The absolute concentrations of certain trace elements in these lakes are given in Table 1 while the concentrations relative to the total dissolved material in the lakes are given in Table 2. The elements were determined by a combination of solvent extraction with cyclohexanone and emission spectroscopy. The method is fully reported elsewhere<sup>8</sup>. Data for Lake Bonney are included for the sake of completeness though they are not discussed in this paper to any extent.

The most significant high relative concentrations of zinc are in Lakes Vanda and Joyce. Lake Hoare is fed by the Canada Glacier on the Asgaard Range, which separates the Taylor and Wright Valleys, while Lake Vanda is fed by melt waters of the Wilson-Piedmont Glacier, the Clarke Glacier, and subsidiary glaciers flowing into the Wright Valley from the Asgaard Range. Accordingly, it is probable that the region of the Asgaard Range near the Canada Glacier may contain significant zinc deposits. This is supported by the occurrence of zinc in Lake Fryxell which is fed by the Canada and Commonwealth Glaciers, both of which are on the Asgaard Range.

The lakes containing the highest relative concentrations of lead are Joyce and Hoare. The former is fed principally by waters from a local glacier with some melt water from the Taylor Glacier. Lead was not detected in Lake Bonney so that the presence of this element in the material in the Taylor Glacier is unlikely. It is therefore probable that lead occurs in the area of the local glacier supplying Joyce and also in the area surrounding Hoare. The relative concentration of lead in Lake Fryxell is considerably less than in Hoare, a similar trend to that shown for zinc. This would seem to imply that the area containing relatively high amounts of zinc and lead in the region of the Canada Glacier does not extend to the Commonwealth Glacier.

Although lead has been shown to be among the most common minor elements in river water<sup>16</sup>, so that it would be expected to be found in waters as concentrated as those considered here (assuming a glacial origin), the fact that it is undetectable in the lakes having the highest concentration of total dissolved material (Bonney and Vanda) makes its relatively high concentration in the others significant.

The high relative concentration of bismuth in Lake Joyce implies a probable deposit of bismuth in this area. This chalcophilic element is often found in galena and it is interesting to note that this lake also contains a high concentration of lead.

Iron constitutes a major fraction of most igneous rocks and would therefore be expected to be present in reasonable concentrations in all lake waters. Although the relative concentration of iron varies appreciably between the lakes, the absolute value, with the exception of Lake Fryxell, remains relatively constant. The concentration therefore seems to be independent of the age or composition of the lake, suggesting a chemical factor influencing the solubility of the iron.

Manganese is also relatively common in igneous rocks and is readily leached from soils and rocks. It is present in river waters in concentrations ranging from 0 to 185 µg/l. with a medium value of 20 µg/l.<sup>17</sup>. As with iron, the variation in absolute concentration is not large, with the exception of Lake Fryxell, and the concentrations of iron and manganese in the lake waters are within the range found in river waters for these elements.

Molybdenum is present in igneous rocks in trace amounts and tends to concentrate in granites, which have been shown to be present in this region<sup>18,19</sup>. It is also commonly found in river waters in concentrations ranging from 0 to 6.9 µg/l.<sup>16</sup>. With the exception of the western lobe of Lake Hoare, the concentration of molybdenum in the lakes lies very close to this range and the variation is therefore most probably not significant.

The above geochemical reconnaissance suggests that the two most likely areas for mineralization in the McMurdo Oasis area of Antarctica are the regions surrounding and

feeding water to Lake Hoare and the region surrounding Lake Joyce. Zinc deposits may also be present in the area between the Lower Wright Valley and Lake Hoare.

## Meteorology and the Great Fire of London, 1666

THE tercentenary of the Great Fire of London (September 2-5, 1666) has given rise to discussion of the incidental meteorological factors. Atallah<sup>1</sup> compares the London fire with that at Hamburg during the Second World War and with the Chicago fire of 1871. He states that the low velocity ground winds at Hamburg and Chicago were ideal for the generation of fire-storms (that is, convection columns in which super-adiabatic atmospheric temperature lapse rates lead to vortices of hurricane force) but that there was no indication of such conditions in the London fire. The purpose of this communication is to consider the inherent (natural) stability or instability of the air mass as a further relevant factor in the manner and intensity of the development of the London fire.

Meteorological evidence for 1666 is limited and any conclusions about the relationship of the fire and the weather must necessarily be somewhat speculative. The summer of 1666 is classified by Shepherd<sup>2</sup> as fine and described by Short<sup>3</sup> as very hot. Samuel Pepys refers, on September 2, 1666, to a long drought, "it being brave dry and moonshine and warm weather . . . and everything, after so long a drought, proving combustible, even the very stones of churches".

The prevailing easterly winds and persistent fine weather<sup>4</sup>, at this time of the year 1666, suggest that atmospheric instability may not have been extreme. Evelyn<sup>4</sup> gives corroborative evidence that smoke from the Great Fire trailed 50 miles in the form of a "column": even allowing for any exaggeration on the part of the diarist, this picture is not what would be expected with a fair wind speed and a steep lapse rate. On the fourth day of the fire (Wednesday, September 5), following a decrease of wind during the previous night, the fire for the first time "lost its capacity for large destruction", and smoke, "having no wind to disperse it, hovered low".

It might be argued that there could have been in September 1666 some persistence of the exceptional instability of the earlier part of the summer and the

preceding spring. There were reports<sup>5</sup> of phenomenal hailstorms on July 17, 1666, in East Anglia, with stones "full as bigg as turkey's eggs" and "one hailstone 12 inches about", and a "great tempest of thunder" and raining fish just before Easter 1666 at Cranstead, Kent. Both the areas mentioned are particularly exposed to winds between easterly and northerly, on the east side of England, and the maximum symptoms of instability were apparently at some distance from the coast; thus the reported phenomena may well be a further manifestation of a period of relaxed westerlies in mid-1666. Again, this state of affairs would agree with the report that 1666 was "a very droughty year"<sup>3</sup>.

The strong instability of spring and early summer might thus be explained by the evidently relaxed westerlies allowing a more marked difference between the heating of land and sea, thus leading to a more intense European monsoon effect. Such instability, however intense, would not necessarily or indeed normally extend into late summer, and all the available evidence suggests that it did not persist in the London area during early September 1666. This assessment of the weather sequence is further supported by the estimate<sup>6</sup> that 1666 was a year of sunspot minimum and by the observed association of a sunspot minimum year with similar unstable weather of transient type<sup>7</sup>.

On the other hand, at Hamburg at 1700 G.M.T. on July 27, 1943 (the day before the night of the fire), an aircraft sounding shows a sharp lapse rate, from 1,000 to 12,000 ft., of 4.8° F (ref. 8); and on the 0700 G.M.T. synoptic weather chart for this day, Germany is situated in a col pressure area (1,015 mbar) between lows over the north-east Atlantic and Russia.

Similarly, in the Chicago region, between October 7 and 10, 1871, the decreasing atmospheric pressure (about 1,005 mbar on October 10 at Detroit) and increasing southerly or south-westerly winds spreading across the area from the west (reaching 34 miles/h on the tenth at Detroit) and changes in pressure, wind and weather generally<sup>9</sup>, reflect a type of disturbed weather which could well be associated with fairly steep lapse rates up to medium levels.

Furthermore, it is not certain that the increasing winds of the Chicago fire were entirely due to a "fire-storm", for there were atmospheric pressure changes which could be expected to lead to an increasing pressure gradient and increasing wind velocities over a wide area. For example, during the 24 h following 0735 h on October 7, 1871, the wind speed at Chicago is reported to have increased from 10 to 19 miles/h, but there were corresponding increases of from 0 to 6 miles/h at Toledo, more than 200 miles to the east, and from 10 to 16 miles/h at Davenport, more than 100 miles to the west<sup>9</sup>.

It is therefore suggested that at the time of the Great Fire of London in 1666 the natural instability of the air mass around London could well have differed substantially from that of the Hamburg and Chicago fires, and atmospheric instability may have been an important differentiating factor in the manner and intensity of fire development.

## THE SOLID STATE

### Methods for interpreting Electron Diffraction Patterns of Thin Alloy Films

THE electron diffraction patterns of thin films of alloys sometimes show fine detail that is not fully understood<sup>1</sup>. Empirical methods of solution are not easy to apply in view of the large number of possible models. We are therefore investigating the possibility of using optical diffraction methods<sup>2</sup>; the diffraction pattern of a mask of punched holes representing an atomic arrangement can be directly compared with the observed electron diffraction pattern.

As an example, we have considered the relatively simple pattern (Fig. 1) given by the alloy Pd<sub>3</sub>Mn (ref. 3). The structure is assumed to be based on a perfect lattice containing anti-phase domains, the unit being the structure postulated by Schubert *et al.*<sup>4</sup>. To simplify the punching of the mask we have represented a palladium atom by a hole and the manganese atom by absence of a hole (Fig. 2); the fine detail of the diffraction pattern is not affected by this procedure, and its intensity is enhanced with respect to the main orders of diffraction. Thus the pattern is clearer than if we had attempted to represent the relative scattering factor of the two atoms.

Because the mask is rather small, we have attempted to incorporate only two types of domain; the complete structure was simulated by making a double exposure of the diffraction pattern with the mask turned through 90°

Fig. 1. Electron diffraction pattern from a thin film of Pd<sub>3</sub>Mn, containing about 25 per cent manganese, annealed from 650° C to 500° C in 28 h. (Originally published in *Trans. Jap. Inst. Met.* **3** (4), 234 (1962).)

Fig. 2. Mask representing atomic positions in Pd<sub>3</sub>Mn.

Fig. 3. Optical diffraction pattern obtained from mask shown in Fig. 2.

in its own plane. The resulting diffraction pattern (Fig. 3) shows excellent agreement with the electron diffraction pattern.

We hope to extend this work to more complicated problems. The method cannot, of course, be complete in itself, as it is only two-dimensional, but we hope that it can provide models that can be tested by more conventional methods. To this end we are proposing to use an optical diffractometer with lenses of 35 cm diameter and 10 m focal length so that far more detail can be inserted in the masks than is possible with the present diffractometer.

### Influence of Heating Rate on Transformations in an 18 per cent Nickel Maraging Steel

SOME observations were made of the effect of heating rate on the martensite (M)→austenite (γ) reversion in a 300-grade 18 per cent nickel maraging steel. These are discussed here with reference to dilatometry, although the conclusions drawn are based also on other sources. Heating rates varied from 0.0037° to 1,200° F/sec, and covered a much wider range than has been reported for alloys of this type<sup>1</sup>. The composition of the material in wt per cent is as follows: 18.40 nickel, 8.86 cobalt, 0.60 titanium, 0.09 aluminium, 0.02 carbon, 0.04 silicon, 0.05 chromium, 0.06 vanadium, 0.008 sulphur, 0.007 phosphorus, 0.016 zirconium, 0.003 boron, 0.05 calcium (added). All specimens were initially in the annealed-martensitic condition.

Heating curves for annealed wire and cylindrical specimens are shown in Figs. 1 and 2, respectively. The inflexion points, denoted by  $T_A$ ,  $T_B$ ,  $T_C$ , and  $T_E$ , are plotted as a function of heating rate in Fig. 3. Up to 40° F/sec these points are displaced to higher temperatures with higher heating rates, which suggests diffusion control. Plots of the logarithm of heating rate, up to 40° F/sec, against  $1/T$  for  $T_A$ ,  $T_B$ , and  $T_C$  give activation energies of about 80 kcal/mole, consistent with values reported for substitutional solute diffusion<sup>2-6</sup> in both α and γ iron.

The dip between  $T_A$  and  $T_B$ , present up to 40° F/sec in the curves of Figs. 1 and 2, is attributed to precipitation.

Precipitates rich in molybdenum, titanium and nickel have been identified as forming during ageing of this alloy<sup>7-9</sup> and serve as nucleation sites for austenite formation. We therefore feel that the large contraction between  $T_B$  and  $T_C$  is due to the M→γ reversion at precipitates, and is referred to as precipitate reversion. Since the γ that is formed would be relatively rich in molybdenum, titanium

Fig. 1. The effect of heating rate on the dilatometric behaviour observed during the heating of a 300-grade 18 per cent nickel maraging steel. Before testing, specimens were annealed at 1,500° F in *vacuo* for 2 h. Wire specimens, resistance-heated, were used for heating rates of between 1.4° and 1,200° F/sec.

Fig. 2. The effect of heating rate on the dilatometric behaviour observed during the heating of a 300-grade 18 per cent nickel maraging steel. Before testing, specimens were annealed at 1,500° F in *vacuo* for 2 h. Cylindrical specimens, furnace-heated, were used for heating rates of between 0.0037° and 8° F/sec.

Fig. 3. Semilogarithmic plots of temperature against heating rate for both wire and cylindrical specimens. Temperatures correspond to the inflexion points on the heating curves of Figs. 1 and 2.

and nickel, which are elements that lower the  $M_s$  point<sup>7,10</sup>, much of this  $\gamma$  iron is retained on subsequent cooling.

During precipitation below  $T_B$  the martensite matrix was largely depleted in nickel; accordingly, the temperature at which  $\gamma$  iron starts to form is raised. The transformation of this nickel-poor M to  $\gamma$ , which is referred to as matrix reversion, is initiated, we believe, at the inflexion point,  $T_C$  (curve 6 of Fig. 1 and curves 2 to 6 of Fig. 2). During both stages of reversion, partitioning of alloying elements occurs between the M and  $\gamma$  phases. The transformation is completed at  $T_D$ ; large composition variations, however, are still present.

At rates above 40° F/sec both precipitation and precipitate reversion are absent. The transformation occurs completely by matrix reversion without any previous change in composition, such as occurs at low heating rates. To distinguish between the presence or absence of such a change in composition, matrix reversion at the high heating rates is designated by  $T_E$  instead of  $T_C$ . Between 40° and 100° F/sec, matrix reversion is accompanied by partitioning of alloying elements, which affects the transformation finish temperature,  $T_D$ . With less time for diffusion at increasingly higher rates, the degree of partitioning decreases rapidly, resulting in a sharp drop in  $T_D$  as a heating rate of 100° F/sec is approached. At still higher rates, diffusion is absent and only minor variations in  $T_E$  and  $T_D$  are observed.

Both  $T_C$  and  $T_E$  represent the initiation of matrix reversion and accordingly are joined in Fig. 3 by an arbitrary curve  $ab$ . Since  $T_C$  is absent on the dilatometric curves for heating rates between 2° and 40° F/sec, it may be that, in this range, matrix reversion is masked by the presence of concurrent precipitation and precipitate reversion. At  $a$  extensive precipitation and alloy depletion of the martensite occur before matrix reversion; at  $b$  this prior behaviour is absent. With an increase in heating rate between  $a$  and  $b$ , less time is available for precipitation, alloy depletion, and precipitate reversion before matrix reversion starts. Thus  $T_C$ , the  $\gamma$ -start temperature for matrix reversion, is lowered from  $a$  to  $b$ . As there is some uncertainty in assigning the data points at  $b$  specifically to  $T_B$ ,  $T_E$ , or  $T_C$ , a combination of symbols is used which represents all three curves.

It would generally be expected that diffusionless reactions should be independent of heating rate. Yet a decrease in reversion temperature is obtained with an increase in heating rate above 40°/sec. This may possibly be related to nucleation sites in the martensitic structure, which may be more readily retained at the elevated temperatures with faster heating rates. This behaviour may also be caused by the presence of two or more competing diffusionless transformations. It has been shown for the case of cooling that different  $M_s$  values are obtained for iron-nickel alloys, and depend on whether the diffusionless reaction is massive or shear<sup>11</sup>. We are now involved in studies directed toward clarifying the dependence of heating rate on the nature and temperature of the transformation. This work was performed under the auspices of the U.S. Atomic Energy Commission.

## Crystal Structure of Solid Hydrogen Chloride and Deuterium Chloride

It has long been known from measurements of specific heat<sup>1</sup> that solid hydrogen chloride undergoes a first order phase transition at about 98.4° K. A similar phase transition was later found<sup>2</sup> in solid deuterium chloride at about 105.0° K. X-ray powder photographs<sup>3</sup> revealed that the crystal structure of hydrogen chloride was orthorhombic below the transition point and cubic above it. They also indicated that the chlorine atoms formed a face-centred lattice in both phases, but gave no clue regarding the location of the hydrogen atoms. Subsequent dielectric constant<sup>4</sup>, infra-red and Raman spectra<sup>5</sup> and nuclear magnetic resonance<sup>6</sup> investigations resulted in a variety of structural models for both phases of solid hydrogen chloride. Nevertheless, the indirect character of the structural information provided by these investigations did not allow an unambiguous choice between the various models.

Table 1

Substance	Temperature (°K $\pm$ 0.2 °K)	No. of observed powder lines	Lattice type	Lattice parameters (Å $\pm$ 0.001 Å)
Hydrogen chloride	92.4	51	face-centred orthorhombic	$a = 5.082$ $b = 5.410$ $c = 5.826$
Deuterium chloride	92.4	41	face-centred orthorhombic	$a = 5.068$ $b = 5.399$ $c = 5.828$
Hydrogen chloride	118.5	21	face-centred cubic	$a = 5.482$
Deuterium chloride	118.5	16	face-centred cubic	$a = 5.475$

To resolve this ambiguity, the structure of solid hydrogen chloride and deuterium chloride was investigated by X-ray and neutron powder diffraction methods. The X-ray powder patterns were recorded photographically using a Weissenberg camera, a temperature-controlled liquid nitrogen cryostat and copper radiation, monochromatized by a curved crystal of lithium fluoride. The results of this investigation are summarized in Table 1. They show (i) that the crystal structures of hydrogen chloride and deuterium chloride are isomorphous, although the unit cell of deuterium chloride is significantly smaller in both phases; (ii) that the reduction in the size of the orthorhombic unit cell of deuterium chloride is strongly anisotropic; it lies almost entirely in the (001) plane. This was interpreted as an indication that the bonds of hydrogen chloride and deuterium chloride are parallel to (001) plane.

The neutron powder patterns were recorded by an automatic neutron diffractometer using a temperature-controlled liquid nitrogen cryostat and crystal monochromatized thermal neutrons of wavelength 1.03 Å. The neutron powder pattern of orthorhombic deuterium chloride recorded at 77.4° K showed several new lines compared with the corresponding X-ray powder pattern. Some of the new lines were due to the cryostat, others to the specimen of deuterium chloride. All deuterium chloride lines could be unambiguously indexed on the basis of the orthorhombic lattice parameters given in Table 1. This confirmed that the orthorhombic unit cell derived from the X-ray powder pattern was the true unit cell of the structure, but it also revealed that the true unit cell was not face-centred as suggested by the X-ray data.

The systematic absences observed in the neutron powder pattern were compatible with two orthorhombic space groups:  $Bbmm$  and  $Bb2_1m$ . The centrosymmetric  $Bbmm$  space group had to be excluded, however, because none of the four-fold special positions allowed by this space group for the deuterium atoms could account for the intensity distribution of the observed neutron powder pattern.

The structure was finally solved on the basis of the non-centrosymmetric  $Bb2_1m$  space group. It was subsequently

Fig. 1.

refined by the least-squares method using all the fifteen integrated intensities which could be derived with sufficient accuracy from the neutron powder pattern. Because of the rather small number of observed intensities, only isotropic thermal parameters were used in the refinement procedure. The results are summarized in Table 2 and a diagram of the structure is shown in Fig. 1. It can be seen that orthorhombic deuterium chloride consists of planar zigzag chains, all oriented in the same way and arranged in layers parallel to the (001) plane.

Table 2. STRUCTURAL DATA OF DEUTERIUM CHLORIDE AT 77.4° K

Lattice parameters:			
$a = 5.053 \pm 0.002$ Å	$b = 5.373 \pm 0.001$ Å	$c = 5.825 \pm 0.002$ Å

Chlorine	0.25	0	0
Isotropic temperature factors of the atoms ( $B$ in Å <sup>2</sup> ):			
Deuterium	$2.7 \pm 0.5$	Chlorine	$1.71 \pm 0.01$
Bond lengths and bond angles in the plane of the chain:			
D-Cl	$1.25 \pm 0.02$ Å	Cl-Cl	$3.688 \pm 0.001$ Å
Cl-Cl-Cl	$93^\circ 31' \pm 2'$		
Final $R$ factor after six cycles of isotropic refinement: $R_1 = 2.9$ per cent.			

The neutron powder pattern of cubic deuterium chloride recorded at 111.5° K showed no new lines compared with the corresponding X-ray powder pattern. This confirmed that the face-centred cubic unit cell derived from the X-ray powder pattern was the true unit cell of the structure. It also indicated that in cubic deuterium chloride the deuterium atoms formed a similar face-centred lattice as the chlorine atoms. No ordered face-centred arrangement of the deuterium atoms could account for the observed intensity distribution of the neutron powder pattern. This discrepancy led to the conclusion that the face-centred cubic structure derived from the powder pattern was only the statistical average of a disordered structure.

Various disordered models were tested, but the small number of the integrated intensities which could be derived with sufficient accuracy from the neutron powder pattern did not allow an unambiguous choice between the models. We are attempting to increase the number of accurately measured integrated intensities by increasing both the angular range and the counting period as far as practicable.

No useful structural information could be extracted from the neutron powder patterns of the solid samples of hydrogen chloride because of the large incoherent scattering of the hydrogen atoms. Nevertheless, the close parallelism between the X-ray powder patterns as well as the specific heat and spectroscopic data of solid hydrogen chloride and deuterium chloride seem to indicate that their structure is isomorphous in both phases.

One of us was the recipient of a grant from the Science Research Council while carrying out this investigation.

### Effect of Pre-yield Relaxation on the Yielding of Iron

THE phenomenon of relaxation before yielding<sup>1-3</sup> has been investigated for polycrystalline iron. Specimens were loaded in tension by a small amount, and then the tensile machine was stopped to permit relaxation to occur. A sequence of such stops was continued until the occurrence of yielding as shown in Table 1. For specimens A-D at 22° C, before yielding, a halt in strain was followed immediately by a reduction of load. By contrast, stopping the machine at about the usual upper yield stress was followed by a period with almost no drop in load after which the specimen suddenly yielded (Fig. 1).

Some of the specimens were made from National Physical Laboratory iron 99.97 per cent pure by weight, with interstitial impurities of 0.0012 per cent carbon and 0.0016 per cent nitrogen. Others were made from this material zone-refined to reduce the interstitial impurities to 0.0004 per cent carbon and 0.0003 per cent nitrogen. Test-pieces with 4 BA threads at each end were machined from 3.2-mm swaged rod, recrystallized at 790° C, and either air-cooled or furnace-cooled (as noted in Table 1). They were then machined electrolytically<sup>4</sup> to uniform gauge sections of length 0.5 cm and diameter between 1.5 and 1.8 mm. In tensile tests these specimens gave the familiar stress-strain curve with a yield drop of up to 50 per cent.

The time allowed for relaxation was 3 min in the pre-yield region, and, after this, relaxation was very slow with a strain-rate of less than  $10^{-7}$  sec<sup>-1</sup>. When the specimen was replaced by massive steel connectors, the relaxation of the system was negligible, so that any load drop with a specimen resulted from deformation of the specimen. The elastic constant of the machine was determined using the massive connectors, a drop in load of 1 kg corresponding to a specimen extension of  $10^{-4}$  cm. The pre-yield stress drops therefore indicate strains of the order of  $10^{-4}$  to  $10^{-3}$ , which are much larger than those found in direct measurements of microstrain in polycrystalline iron<sup>5</sup>. It seems likely that at lower loads part of this strain arose from

\* Specimen connectors knocked during relaxation, and increased load drop resulted.

post-yield relaxation of a small volume of material at stress concentrations in the specimen threads. It has been shown in associated work that the post-yield relaxation of iron is roughly constant up to 50 per cent extension, so that relaxation at the threads could continue to higher loads. At the 22°C yield point in these tests, however, there was initially no drop in load and, since there is no apparent reason for relaxation at specimen threads to decrease abruptly, this must mean that any such relaxation has become negligible, presumably because the threads bed-in.

The observed relaxation at stresses approaching the upper yield stress is therefore attributed to dislocation movement in the gauge length of the specimen. It has then to be explained why at the yield point there was a delay period with no measurable relaxation, followed by sudden yielding. The absence of relaxation indicates that the number of free dislocations, or of dislocation sources which could operate at the yield stress, was much reduced by the loading programme. This is supported by the observation that, on successive reloading to the same stress in the pre-yield region, the stress drop was much reduced (see Table 1 and ref. 2). The dislocations set moving during each stress increment will slow down during the subsequent relaxation, and there could be partial loss or relocking of dislocations; this could give a slower build-up of dislocation movement before the upper yield point than in a normal test. A large amount of dislocation movement could, however, still occur without being apparent, because the limit of detection of overall strain was  $2 \times 10^{-5}$ . The delay period could then be explained by an unlocking process; and since the delay is so long this indicates that to produce yielding a co-operative interaction of a large number of dislocations is required, which might be a piling of dislocations against grain boundaries, followed by a sudden release of fresh multiplying dislocations. Alternatively, the yield process might be dynamic, and require a critical amount of movement or momentum to be attained in part of the dislocation network to give

an unstable system and rapid multiplication, in which case obstruction to moving dislocations rather than unlocking could be the controlling factor. The experiments so far made do not distinguish between these explanations.

Delayed yielding is normally associated with fast strain-rates<sup>6-10</sup>, when for low stress delay times of several seconds are found at room temperature and up to 80 sec at low temperatures. Hutchison and Louat investigated for Armeo iron the effect of preloading at 65°, 100° and 150° C on the yield stress in a conventional tensile test at room temperature, and found that this was increased<sup>11</sup>; they did not report any change in the form of yield. The work most closely related to the present is that of Owen *et al.*<sup>12</sup> on pre-yield phenomena in mild steel. Some

Fig. 1. Pre-yield relaxation followed by sudden yielding, in iron at 22°C. A, Pure iron, furnace-cooled, grain size 4.0 mm<sup>-0.5</sup>, area 2.55 mm<sup>2</sup>; B, zone-refined iron, air-cooled, grain size 3.9 mm<sup>-0.5</sup>, area 2.18 mm<sup>2</sup>; C, pure iron, air-cooled, grain size 4.0 mm<sup>-0.5</sup>, area 1.54 mm<sup>2</sup>; D, pure iron, furnace-cooled, grain size 4.0 mm<sup>-0.5</sup>, area 1.66 mm<sup>2</sup>. (Actual strain-rate  $1.7 \times 10^{-4} \text{ sec}^{-1}$  for curve A,  $1.7 \times 10^{-5} \text{ sec}^{-1}$  for B, C, D.)

specimens were extended at a low rate to a predetermined stress, held for several minutes, unloaded, and subsequently reloaded to a higher stress; a long period of microstrain (microcreep) preceding gross yield was obtained at liquid nitrogen temperature, but not at room temperature.

To check the effect of temperature with the present loading procedure, specimens were tested at  $-80^{\circ}\text{C}$  ( $E-H$  in Table 1). All gave a greater drop in load on relaxation in the pre-yield region than at  $22^{\circ}\text{C}$ . Specimens  $G$  and  $H$  yielded during a period of straining, at stresses of 28 and 15 kg/mm<sup>2</sup>, and their behaviour differed from that in a conventional test at  $-80^{\circ}\text{C}$  (see Table 1: the normal upper and lower yield stresses were 34 and 24 kg/mm<sup>2</sup>). Specimens  $E$  and  $F$  gave similar behaviour to that at  $22^{\circ}\text{C}$ , with sudden yielding during relaxation at about the upper yield stress, and delay times of 36 and 126 sec; however, there was a slow fall in load before the sudden yielding, and the fall in load on yielding was not so abrupt as at  $22^{\circ}\text{C}$ . These results accord with the effects of temperature already noted, showing greater dislocation movement at  $-80^{\circ}\text{C}$  than at  $22^{\circ}\text{C}$ .

The present work shows that the yield behaviour of iron when loading at conventional strain-rates depends on the loading programme. In interpreting these or other delay time experiments it is necessary to consider not only the unlocking of dislocations, but also the possibility that the mechanism controlling yield is the multiplication of free dislocations.

The work described above has been carried out at the National Physical Laboratory, with the participation of Miss J. M. Hills.

## CHEMISTRY

### A New Type of *bis*-(Acetylacetonato)metal(II) Polymer: the Trimer of *bis*-(Acetylacetonato) Zinc

THE versatility of acetylacetonate (acac) as a ligand is well documented<sup>1</sup>. It forms metal complexes of the following structural types: (1) normal chelate compounds<sup>2,3</sup>, (2) polynuclear bridged species<sup>4-6</sup>, (3)  $\gamma$ -carbon bonded complexes<sup>7,8</sup>, and (4) condensation products formed from complexes of the third category<sup>9</sup>. We report here the structure of  $[\text{Zn}(\text{acac})_2]_3$ , which is an example of the second type with a new kind of stereochemistry in which zinc exhibits both five and six co-ordination.

Bullen, Mason and Pauling<sup>4</sup> inferred but could not prove a trimeric structure from preliminary cell measurements (now found to correspond to the non-standard monoclinic space group  $F2$ ). Recent measurements in this laboratory indicated possible space groups  $C2/m$ ,  $C2$  or  $Cm$ , with unit cell parameters of  $a=18.63$ ,  $b=8.437$ ,  $c=12.20$ , and  $\beta=112.68^{\circ}$ . The intensities of 1,928 reflexions were collected on a manual diffractometer; the Patterson synthesis unambiguously determined the space group as  $C2$ . The structure was solved by conventional Fourier and

Fig. 1. Stereochemistry of  $\text{Zn}_3(\text{acac})_6$ . Carbon atoms of acetylacetonate ligands are omitted for clarity. The "octahedron" about the central zinc atom is appreciably distorted. The main deviations from  $90^{\circ}$  angles are in those marked as  $\alpha$ ,  $\beta$  and  $\gamma$  on the sketch;  $\alpha=75.1^{\circ}$ ;  $\beta=105.8^{\circ}$ ;  $\gamma=101.7^{\circ}$ . Other angles are within  $4^{\circ}$  of  $90^{\circ}$ . The arrangement of oxygen atoms about the terminal zinc atoms approximates fairly closely (average deviation  $5^{\circ}$ ) to that for a trigonal bipyramid.

least squares techniques and has refined isotropically to a present reliability index,  $(\Sigma||F_o| - |F_c||)/\Sigma|F_o|$ , of 0.08.

The main features of the molecular structure are shown in Fig. 1. The crystallographic and molecular  $C_2$  axes are coincident and contain the central octahedrally co-ordinated zinc atom. The two terminal zinc atoms have a slightly distorted trigonal bipyramidal co-ordination. Unlike  $\text{Ni}_3(\text{acac})_6$  (ref. 4) and  $\text{Co}_3(\text{acac})_6$  (ref. 5),  $\text{Zn}_3(\text{acac})_6$  contains no acetylacetonate ligands with both oxygens serving as bridges. The relative stability of pentaco-ordinate zinc in this system is evidenced by the preferential formation of products of the type  $\text{Zn}(\text{acac})_2L$  over  $\text{Zn}(\text{acac})_2L_2$  complexes<sup>2,3,10</sup>. The presence of the central octahedrally co-ordinated zinc atom indicates, however, that the difference in stability is not large because otherwise one might expect a structure involving only five-co-ordinate zinc, such as the dimer of trigonal bipyramids reported for *bis*(*N*-methylsalicylaldiminato)zinc(II) (ref. 11). Thus, the tendency of  $M(\text{acac})_2$  molecules to form polymers can be said to result from the preference of the metal atoms for co-ordination numbers higher than 4, but not necessarily for a co-ordination number of 6. These polynuclear structures have been different in each of the three compounds so far structurally characterized (for  $M=\text{Ni}$ ,  $\text{Co}$ ,  $\text{Zn}$ ) and the structures are evidently quite sensitive to the stereochemical idiosyncrasies of the individual metal ions.

A detailed report of the results of this investigation will be submitted when further refinement, including absorption corrections and a weighting scheme, is complete. The work was supported by the U.S. National Science Foundation. One of us (R. E.) is a Union Carbide predoctoral fellow.

## Dipole Moment and Microwave Spectrum of Bromo-acetylene

THE electric dipole moments of the mono-halogen acetylenes are known to decrease to very small values as the electronegativity of the halogen decreases. The moment of bromo-acetylene, in particular, was reported to be indistinguishable from zero by Brockway and Coop<sup>1</sup>. Although no estimates of possible errors were stated for this molecule, the accuracy of the methods was in general such that the error was not expected to exceed 0.01 D. Tyler and Sheridan<sup>2</sup> prepared and characterized iodo-acetylene, and were unable to detect its microwave spectrum in sensitive instruments, although the  $B_0$  value assumed was subsequently proved to be correct by rotational Raman spectroscopy<sup>3</sup>. Hence it was concluded that the dipole moment of iodo-acetylene is not more than 0.05 D, perhaps much less. In view of the improbability that bromo- and iodo-acetylene should both possess such small dipole moments, we have examined the microwave rotation spectrum of bromo-acetylene. This spectrum proved easy to observe and indicated that the dipole moment of the molecule is more than 0.01 D.

The  $J = 2 \rightarrow 3$  and  $3 \rightarrow 4$  transitions were measured for <sup>79</sup>BrCCH and <sup>81</sup>BrCCH, and the  $J = 2 \rightarrow 3$  transitions for <sup>79</sup>BrCCD and <sup>81</sup>BrCCD. High electrostatic fields were required, as expected, for the production of resolvable Stark effects in the lines of the molecular ground states, but well resolved splittings were observed at fields of several thousand volts per cm. The nuclear quadrupole fine-structures, which showed the expected second-order perturbations, were analysed to give the following spectroscopic constants.

Table 1		
Molecule	$B_0$ (Mc/s $\pm$ 0.03 Mc/s)	eqQ of bromine (Mc/s $\pm$ 2 Mc/s)
<sup>79</sup> BrCCH	4,000.05	646
<sup>81</sup> BrCCH	3,978.44	541
<sup>79</sup> BrCCD	3,655.11	646
<sup>81</sup> BrCCD	3,634.98	541

Spectra caused by molecules excited in the bending-modes  $\omega_4$  and  $\omega_5$  were also easily observed, and distinguished by their much stronger Stark effects. The analysis of their overlapped fine-structures is in progress. Details of the Stark effects are being analysed to obtain accurate dipole moments in the ground- and vibrational-states. The preliminary indications are that the moment is of the order of 0.1 D.

The values of  $B_0$  yield a substitution bromine-hydrogen distance of 4.051 Å. From the inertial contributions of the carbon atoms, and the mass-centre condition, the bond lengths are derived with less accuracy as: bromine-carbon = 1.784 Å, carbon-carbon = 1.216 Å, and carbon-hydrogen = 1.051 Å. They agree well with the electron diffraction data<sup>1</sup> and expectations based on results for related substances<sup>2</sup>. The nuclear quadrupole coupling constants are very close to those found in methyl bromo-acetylene<sup>4</sup>.

The strength of the spectra indicates that work now in progress on species containing carbon-13 in natural concentration should lead to a more accurate complete set of bond lengths by the substitution method.

## RADIOBIOLOGY

### Killing and Mutagenic Efficiencies of Heavy Ionizing Particles in *Arabidopsis thaliana*

THE killing and mutagenic effects of heavy ionizing particles, helium, carbon and argon, accelerated by an energy of 10.4 MeV/nucleon were investigated and compared with the effects produced by caesium-137 gamma-rays. The effects of heavy ions on several biological systems have been discussed by Brustad<sup>1</sup>, Tobias<sup>2</sup> and by Deering *et al.*<sup>3</sup>.

*Arabidopsis thaliana* (L.) Heynh. was used in this experiment. Dry  $F_2$  seeds obtained from  $F_1$  hybrids between a hairless mutant ( $gl^1$ ) and the wild hairy strain of race 'Landsberg' were subjected to gamma-rays and heavy ionizing particles.  $F_2$  seeds were used because it is difficult to obtain many  $F_1$  seeds<sup>4</sup>. Irradiation with heavy ionizing particles was carried out on a 'Hilac' machine<sup>5</sup>, and the dose rate for all irradiations was about 4-5 krad/min. The irradiations were carried out in air; before the beam reaches the seeds, it has first to penetrate various absorbers the thickness of which is equivalent to 12.7 mg/cm<sup>2</sup> of aluminium. Dry seeds were subjected to a surface dose of 1-5 krad of helium-4 and carbon-12 ions and 3 and 5 krad of argon-40 ions with initial particle energies of 41.6, 124.8 and 416 MeV respectively. To compare relative biological effectiveness (RBE) and establish a standard, 27 and 47 krad gamma-ray exposures were given to the same material at an intensity of 10 krad/h using a 6 kc. caesium-137 source. The seeds were sown about 30 h after the gamma-ray treatment.

Germination and survival rates in the control and in the two portions irradiated by gamma-rays were very high, amounting to about 90 per cent. Survival rates decreased markedly with increasing dosage in the portions irradiated by heavy ions, especially those treated with helium ions. Survival rate in the portions irradiated by a 5 krad dose of helium ions was reduced to about half of that in the control portion. The decrease of survival rates in portions irradiated by carbon ions was not so severe, and was about 66 per cent in the portion receiving the highest dosage. On the other hand, 3 and 5 krad treatment with argon ions showed a slight decrease of survival rate (Table 1).

Table 1. SEGREGATION RATIO AND MUTATION RATES IN IRRADIATED  $F_2$  POPULATIONS

Treatment (krad)	No. of seeds	Percentage of survivals	Hairy	Hairless	Expected No. of heterozygotes	No. of plants with hairless sectors (per cent)

About 67 per cent of the hairy plants can be assumed to be heterozygotes for the hairy hairless allele pair, so to find somatic mutation from dominant hairy to recessive hairless we had to look among those plants. The number per individual of mutated hairless leaves or leaf sectors showed a variation. When a leaf or a part of a leaf was hairless it was scored as one mutational event occurring in the dominant hairy allele, without reference to the number of mutated leaves or sectors per individual, in order to compare the relative mutation rates. The rates calculated by this method may not be equivalent to the real mutation frequencies, but they are useful for comparing

Fig. 1. Somatic mutation rates.

the mutation frequency induced by gamma-ray irradiation and heavy ionizing particles.

The frequency of plants with hairless sectors increased with increasing dosage in gamma-ray, carbon ion, and argon ion portions as shown in Table 1. Somatic mutation rates in the carbon ion portions were very high; those of argon ion portions were very much lower. On the other hand, only one mutated plant was observed in the portion irradiated by 2 krad helium ions, and the other 4 portions treated with helium ions showed no mutation. Irradiation experiments with helium ions were carried out again with a dose of 1 to 4 krad, but again no mutation was observed; a severe killing effect was found, however, which was in good agreement with the preceding experiments.

As shown in Fig. 1, curves of dose against mutation for the carbon and argon ion portions were fairly linear while an exponential curve was observed between mutation frequency and gamma-ray dosage. We could not draw a curve of dose against mutation frequency for the helium ion portion, because only one mutated plant occurred, although the experiment was repeated. A similar exponential curve for somatic mutation in gamma-ray treatments has previously been observed by Fujii<sup>4</sup>, and also an almost linear curve in neutron treatments. The exponential relation tends to predominate in radiations of low linear energy transfer (LET), such as gamma-rays and most X-rays, and at high doses or dose rates; the linear relation dominates in high LET tracks in general and at low doses or dose rates<sup>5,6</sup>. The shapes of dose-response curves are therefore different, and the RBE value of heavy ionizing particles cannot be expressed by a single parameter. The frequencies of somatic mutations of gamma-rays and heavy ionizing particles were compared at 0.5 per cent mutation rates from their dose against frequency curves. About 33 krad of gamma-rays was necessary to produce the 0.5 per cent mutation rate, and about 0.9 and 6.7 krad of carbon ion and argon ions could produce the same mutation frequency. From the results, RBE for somatic mutation at 0.5 per cent frequency was roughly estimated as 35 for carbon ions and 5 for argon ions. We were also unable to decide about the RBE of helium ions, but if the mutation rate shown by the 2 krad portion was sustained, their RBE for somatic mutation might be about 10.

The calculated RBE value for argon ions is rather tentative, since there remains the question of the penetration of the ion beams. The seeds were attached to filter paper and were irradiated with heavy particles. Because of their ellipsoidal shape, most of the seeds lie flat on the filter paper. We may therefore assume that the accelerated ion beams of heavy particles penetrate most seeds laterally and only a few longitudinally. The width of the seeds is about 0.28 mm, that is an average of 28 mg/cm<sup>2</sup>; and argon ions which have a residual range of 12.6 mg/cm<sup>2</sup> in

the tissue must be stopped within the seeds. These ions presumably cannot pass through the seeds, but they can penetrate into seed tissue, and might attack the embryo which is located almost in the centre of the seed. The residual range of helium ions and carbon ions is 133 and 47 mg/cm<sup>2</sup> respectively; these ions certainly can penetrate and pass through the seed tissue.

This research was partly supported by the U.S. Atomic Energy Commission and the U.S. National Aeronautics and Space Administration.

### Increased Radiosensitivity in *Lens esculentum* Seeds irradiated in a Mononucleotide Solution

We know from previous work that it is possible to incorporate a mononucleotide into a polynucleotide by means of  $\gamma$ -radiation<sup>1-4</sup>. This communication describes the results of some experiments which we have carried out to explore the possibility that a similar model could be applied to biological systems and could take into account the development of mutations.

The method used was as follows: two groups of *Lens esculentum* seeds (I and IV) were incubated for 3 h in water and in a 0.02 molar solution of uridylic acid-2'-3' (UMP-2'-3'), respectively, and irradiated with a caesium-137 source at a rate of about 200 r./min and a total dose of  $6 \times 10^4$  r. Two control groups (III and IV) were handled in a similar fashion, but not irradiated. The four groups were planted on wet filter papers and the number of roots and cotyledons counted daily.

The data were plotted according to equation (1)

$$\log_e (1 - N/N_0) = A - Ct \quad (1)$$

where  $t$  is the time after irradiation,  $N_0$  is the total number of seeds in a group, and  $N/N_0$  is the fraction of seeds that have roots or cotyledons. In this equation the fraction of seeds without germination (or without cotyledons in the other case) is a logarithmic function of time after irradiation, at a given dose. We calculated the best line that fits our data; the regression equations for each group are shown in Table 1. As can be seen in Fig. 1 each group is characterized by a different slope. Lines (1) and (2) have statistically different slopes, but the main difference is their respective value for the constant  $A$ . On the other hand,  $A$  has approximately the same value in lines (3) and (4) (within the experimental error), but the lines have statistically different slopes. Furthermore, the slopes of these last lines are statistically different from the slopes of lines (1) and (2). Similar observations can be drawn from the lines shown in Fig. 2, which correspond to the development of cotyledons.

As we did not detect any damage in the seeds irradiated in water, and even observed a slight stimulation in their development, we assume that the relatively small dose of radiation used increased the total number of totipotential cells. It is remarkable that in the group of seeds irradiated with mononucleotide, the increasing effect on the initial

process of cell multiplication and on the velocity of development, due to the irradiation, is absent. The mononucleotide on its own, however, has an inhibitory effect, which is increased in the presence of radiation and persists throughout the experiment.

In accordance with equation (1), which describes the damage to the seeds, a greater slope corresponds to a smaller damage. If we calculate the time taken to reach  $T_{37}$  (the point at which 37 per cent of the seeds are without roots or cotyledons), it is obvious that this gives directly an equivalent of the usual "sensitive volume" of the system and that is due to the sort of inverse plotting (as compared

with the usual one) which we adopted for graphs (1) and (2). Table 2 summarizes the sensitive volume of the two processes as the appearance of roots and cotyledons. Except for group IV the sensitive volume for the development of the cotyledons is larger than the volume obtained when the appearance of roots is measured. Moreover with seeds irradiated in water there is a decrease in this sensitive volume, which is greater for cotyledonary processes, in accordance with the slope of their respective regression lines. On the contrary, with irradiated seeds treated with nucleotide we find no difference between this sensitive volume of roots and the development of cotyledons; furthermore, these two sensitive volumes are the largest found, and about four times greater than those of the control seeds (group II) for root processes and twice for cotyledonary processes.

It is possible to imagine that seeds which are treated with mononucleotide and nucleotide plus radiation become damaged in such a way as to prevent normal growth and differentiation. The seeds treated with only nucleotide have a retarded development, and therefore we can interpret this persistent damage as arising from a high concentration of one mononucleotide inside the cell, in relation to the others; such a difference could promote a greater chance of error in the copying of genetic information for the processes of root growth and appearance of cotyledons. It follows from our data that the amount of damage is still greater in seeds irradiated in solutions of mononucleotide because here the sensitive volume of the two processes is equal, possibly as a result of a shared damage.

Bearing in mind our earlier findings and reports concerning the incorporation of mononucleotide into polynucleotide by  $\gamma$ -radiation, we can postulate that the greater cell damage in group IV is a consequence of the incorpora-

tion of nucleotide into the cellular DNA or RNA. The damage remains throughout the experiment and for many cycles of cellular replication. It also inhibits the two processes studied, and is therefore more likely to involve damage of the DNA, especially as in seeds mRNA has a life of about 2 h (ref. 5).

With the view of gaining a better understanding of the mechanism of the cellular damage described here, we are continuing our experiments, and are especially looking out for the specificity of the nucleotide damage induced when seeds are irradiated.

We thank R. Jiménez, I. Saavedra and H. Reitbock for encouragement and helpful discussions, and the Experimental Station "La Platina" (Ministerio de Agricultura) for the seeds used in this investigation, which was partially supported by a grant from the International Atomic Energy Agency.

### Direct and Indirect Effects of Radiation: the Radiolysis of Sugar

OUR earlier communication<sup>1</sup> presented evidence that important biological consequences accrue from the presence of stable chemical products of radiolysis which are derived from sugar in the ambient culture media of plant cells or tissue explants. These effects became evident because they neutralized the effect of growth stimulatory substances which induce cell division and cause otherwise quiescent cells to grow rapidly. Thus the potency of the effect of radiated sugar could be assayed. We also showed that growth in the presence of the radiolysis products of sugar may result in abnormal mitotic and meiotic chromosomes in other types of material (root tips and pollen mother cells).

In selected earlier works, we<sup>1</sup> found some claims that products of irradiation of the external medium could exert effects on cells and organisms with which they come into contact; these effects are termed indirect. The work of Phillips<sup>2,3</sup> also showed that much is known about the radiolysis of sugars.

There is other evidence for indirect biological effects of radiation. Chopra has detected such effects by increased mutations of bacteria<sup>4</sup>; Berry *et al.* have recognized cytotoxic effects on human and animal cells<sup>5</sup>, and Rinehart and Ratty saw a significant increase in sex-linked recessive lethals in *Drosophila*<sup>6</sup>, but of particular importance is the work of Shaw<sup>7</sup> on human cells in culture. The adverse comments of Goldblith<sup>8</sup> do not require further notice<sup>9</sup>.

Later work has been carried out in an attempt to isolate and identify the biologically active constituents in the many radiolysis products from sugar which has been exposed to radiation from a cobalt-60 source. Previously some furan derivatives of known structure, which were isolated after fructose breakdown under acidic conditions by Dr. C. T. Moye in Australia, were supplied to us for test in our assay conditions. Some of these exhibited ultra-violet absorbance, but others did not. Our tests so far show that these compounds were neither identical with

the most potent fractions from irradiated sugar nor were they similarly active in our assay system.

Some 280 g of sucrose (as a 2 per cent aqueous solution) were irradiated in batches (2 megarads delivered during a 2-h period). From this material, 263 g of unchanged, biologically neutral, cane sugar were recovered, as well as 476 mg of a white crystalline compound which suppressed growth. This proved to be a salt of formic acid—possibly derived from formaldehyde. The formic acid (as its sodium salt) was critically identified by chemical analysis and by infra-red absorption spectra and nuclear magnetic resonance; the identification in the Cornell laboratories was made with the help of Dr. J. Meinwald of the Department of Chemistry and was carried out independently by Dr. Sugii, then in Japan. Neither the data which prove this identification nor the assay data which record the biological activity will be reported here. It can, however, be stated that on both points the evidence was unequivocal. How far the formic acid contributes to both the cytotoxic and to the cytological or genetic effects is, however, not yet known. At the same time, approximately 1 g of crude, yellow syrup of high ultra-violet absorbance (at 265 mμ), analogous to that previously described<sup>1</sup>, was isolated. This fraction definitely inhibited growth in the carrot assay system. With the help of Dr. E. M. Shantz of this laboratory, this material has been still further purified and fractionated on activated charcoal and silica gel columns. We have obtained various subfractions which show both ultra-violet absorbance and varying effects in the culture system. Among these subfractions are some which are inhibitory in the carrot explant assay system, but the identification of any one fraction, or the evaluation of their interactions, is still incomplete. Similar tests made on irradiated glucose and fructose have produced comparable biological results.

Although the evidence is incomplete, there can be no doubt that when sucrose, as pure as this reagent can be, is in de-ionized distilled water a certain percentage of its total carbon is converted to other compounds under the influence of γ-radiation from cobalt-60. The number of compounds so formed is widely known to be large. Among the acidic compounds which did not absorb ultra-violet light is formic acid, but the most elusive biologically active compounds are among those which have characteristic ultra-violet absorption spectra in acidic and alkaline solution, and which are separable by column chromatography into several components.

The inhibitory effects of these radiolysis products on growth have been preserved during storage for long periods at low temperatures, at least when the products have been autoclaved in the appropriate media before use. When the active substances are fully identified, however, it may be possible for them to be assayed in such complex media as radiated foods, and their longevity and stability when subjected to varying treatments in various media may be determined, and they will be tested against a variety of different assay systems.

## BIOPHYSICS

Guard-rings, Surface Films and Artefacts  
in the Viscometry of Human  
Blood

THE realization that blood is a non-Newtonian and shear-thinning or thixotropic fluid is quite recent, and in great measure is due to the pioneering efforts of Wells and Merrill<sup>1,2</sup>, who first used a 'Brookfield' cone-plate viscometer and later a more complex coaxial-cylinder viscometer. Shortly afterwards, however, they observed<sup>3</sup> some artefacts which influenced their viscosity readings and which they attributed to the formation of a rigid surface film, which was believed to transmit torque from the rotating to the suspended member of the viscometer. Believing that their observations negated the existence or the amount of shear-thinning in blood at low rates of shear (in the vicinity of  $1 \text{ sec}^{-1}$ ), they rejected some of their earlier data.

In my studies of blood viscosity and thixotropy, I have used a cone-in-cone viscometer since the beginning of 1961, and freshly shed blood without anticoagulants. The data observed were reported in a series of publications<sup>4,5</sup> and led to some suggestions on the role of high blood viscosity, especially at low shear rates (0.01 to 1 reciprocal second), in circulatory diseases and in the pathogenesis of thrombosis.

Following the suggestion by Wells<sup>6</sup> that the results obtained by means of my cone-in-cone viscometer should also be affected by the formation of a "rigid surface film", I decided to investigate this phenomenon more closely. In this I used guard-rings which according to Wells and Merrill should prevent the transmission of a torque from the rotating to the suspended member, and thus avoid the effects of the rigid surface film.

Five guard-rings were made from 'Teflon'; three had cylindrical and two conical geometry. The gaps between the edge of the inner cone and the inner surface of the guard-rings varied from  $16 \times 10^{-3}$  to  $120 \times 10^{-3}$  in. (from 0.4 to 3 mm). Tests were carried out on water, low-viscosity paraffin oil, freshly shed and fresh anticoagulated blood, and one-week-old plasma and blood.

The tests carried out on distilled water showed that stationary guard-rings decrease deflexions of the inner cone to a considerable extent. The diameter of the ring is of no great importance, although some small variations in deflexions (up to 10 per cent at high speeds) were observed. The addition of a detergent markedly reduces the deflexions obtained in the absence of guard-rings, and reduces the discrepancy observed between deflexions in the presence and in the absence of stationary guard-rings. The discrepancy is proportional to the angular velocity of the external cone.

The addition of detergent to water, when any of the guard-rings is used, makes very little if any difference to the deflexions of the internal cone.

The rings were tested not only in a stationary position (which is proper for the guard-ring), but they also were allowed to rotate with the external cone in order to estimate the additional drag caused by their presence. Drag was small or negligible in the presence of a drop of detergent; without detergent, the drag was highest for the smallest ring, and absent for the largest ring. The effect of detergent suggests that some phenomenon related to surface tension is involved.

When low viscosity paraffin oil (3 to 5 centipoises) of Newtonian rheology was used, the deflexions were always proportional to the angular velocity of the external cone. The "braking" or "accelerating" action of the ring was caused by the ring being stationary or rotating with the external cone, respectively. The mean value of the deflexions of the inner cone, obtained in both ways, was nearly identical (within 1 to 2 per cent) to the deflexion observed in the absence of rings. It suggests that no

surface film of any consequence is present on the surface of paraffin oil.

The situation becomes much more complex when blood is used. In the first series of experiments, freshly shed blood was collected into a plastic syringe containing heparin as anticoagulant. The large ring, which rides on the edge of the external cone, did not affect the deflexions (or blood viscosity reading) at any rate of shear. The small ring, on the other hand, acted as a single unit with the inner cone; that is, when stationary, it locked the inner cone in a stationary position; when rotating, it locked the inner cone and caused it to rotate at the angular velocity of the rotating cone. The intermediate rings behaved in an intermediate manner; that is, when stationary, they caused a "braking" effect and decreased the deflexion of the inner cone; when rotating, they induced a higher deflexion of the inner cone.

Further tests on older blood and on plasma showed that, in general, the action of the guard-rings depends on the gap existing between the inner surface of the ring and the edge of the inner cone. The rings had no effect in one-hour old plasma or one-hour-old anticoagulated blood if this gap was larger than 0.056 in. (1.42 mm). A strong braking and/or locking effect was found in anticoagulated blood more than a few minutes old, when the gap was less than 0.033 in. (0.84 mm). Locking-braking actions could be observed with intermediate rings, the effect depending on the age of the blood and increasing with the age of the blood. Consequently, even a ring of large diameter could lock the inner cone, if the blood was old enough.

These experiments indicate the following:

(1) The nature of the film formed at the blood-air interface is completely different from that observed on the distilled water air interface. (2) The effect of this film on the blood viscosity test depends on the geometry of the guard-ring used. Although a small ring may act as a complete brake and may lock the inner cone, a large ring may have no effect whatsoever. (3) The action of a guard-ring depends on the age of blood used, and the locking and braking effects increase with the age of the blood. (4) In the systems in which a ring acts as a partial brake or a partial accelerator, the effect is roughly proportional to the angular velocity of the external cone. (5) In freshly shed (not anticoagulated) blood, the presence of large and intermediate size rings is of no importance.

It does seem, then, that there is no rigid surface film formed on freshly shed blood in the cone-in-cone viscometer. If a film of the type described by Wells and Merrill were present, the application of any guard-ring would be noticeable, and the geometry of the ring would not be important.

It must be concluded that while a surface film is formed on anticoagulated blood, it is a peculiar property of this film that its action decreases with the increasing gap between the inner and the outer member of the viscometer. Another peculiar property of this film is that it increases in strength when blood ages.

It is possible that the low magnitude of the surface effects in the cone-in-cone viscometer, and their complete absence in the freshly shed blood, is a lucky consequence of the fact that the gap between the inner and outer cone edges is about 1.8 to 2 mm. It is quite likely that in instruments with very narrow gaps, such surface films might be very noticeable. The critical "locking" range (up to 0.8–1 mm) may, however, be quite different in the narrow-gap instruments. The ratio of the frictional area of the suspended member to the frictional effects of the guard-ring might be relevant, and will be quite different in viscometers of different geometries.

While these experiments with guard-rings of different geometry confirm the validity of viscosity data obtained on freshly shed blood by means of the cone-in-cone viscometer, they raise many interesting questions. The molecular structure of this surface film on blood or the nature of the "surface film" in distilled water are matters

of speculation. One may wonder whether the rejection of their earlier data by Wells and Merrill was not too hasty; perhaps a guard-ring of another geometry might have behaved differently.

## PHYSIOLOGY

### Movement of Solutes across Luminal Cell Membranes in Kidney Tubules of the Rabbit

SLICES of kidney cortex have been used to advantage in the investigation of the mechanism of renal transport systems<sup>1</sup>, although the technique has definite limitations. Thus it could be calculated that the contribution of the membrane which separates the cell from the tubular lumen (luminal membrane) to the turnover of paramino hippurate in slices is negligible<sup>2</sup>. Similarly, the luminal membrane appears to play no part in the turnover of potassium in slices<sup>3</sup>; only the peritubular membrane seems to be involved here. Among possible reasons for this is the length of the path of diffusion through the convoluted tubule and/or the collapse of the tubular lumen as a result of continued reabsorption of salt and water<sup>4</sup>. The influence of the length of the tubule is seen, for example, in a preparation of teased flounder kidney. In this case, efflux of dyes from the lumen is dependent on energy<sup>5</sup>, which suggests that the path of efflux lies across the cell and that there is little loss of dye directly from the lumen to the medium.

Some of the inherent limitations of the technique which employs slices can be overcome by the use of fragments of tubules<sup>6</sup>. In such a preparation the destruction of tubular architecture causes the exposure of luminal cell membranes to the incubation medium. This is illustrated in Fig. 1 which shows a comparison of solute fluxes in fragments and slices. It further indicates that in physiological conditions the net passage of sodium out of the cell during the process of reabsorption of sodium occurs across the peritubular membrane. In contrast, paramino hippurate is transported through the cell across the luminal membrane in the opposite direction. It is only in fragments, therefore, that the efflux of paramino hippurate from cells can be measured in the normal physiological sense. The unmasking of the luminal membrane on fragmentation of the tubule is thus expected to cause a greater acceleration of efflux of paramino hippurate and other secreted substances than of sodium.

To test this hypothesis tissues were preloaded with either sodium-22 or paramino hippurate or tetraethylammonium labelled with carbon-14 by incubation with these substances at 28° C for 30–40 min. For the accumulation of sodium-22, Ringer's solution free of potassium was used. Solute efflux was followed in tissues suspended in Ringer solution (free of paramino hippurate or tetraethylammonium) after washing in an isotonic solution of choline chloride (for efflux of sodium-22) or saline (carbon-14). Washing of fragments involved centrifuga-

Fig. 1. Schematic presentation of efflux of sodium and paramino hippurate (PAH) from slices and fragments. PTM, Peritubular cell membrane; LM, luminal cell membrane; ISF, interstitial fluid. Thickness of arrows indicates relative magnitude of net fluxes. Note that in slices the presence of the lumen effectively prevents the return of solute from cell to medium across the luminal membrane. For further details, see text.

tion and resuspension in solution kept ice-cold by the addition of crushed frozen pieces of the same solution; this slurry was again spun down, and the packed washed cells were resuspended in efflux medium. Rapid separation of fragments from efflux medium was achieved by filtration on a Buchner funnel fitted with Whatman No. 541 filter paper. The fall in the concentration of tracer in the tissue was determined at time intervals selected so that the final percentage activities remaining in slices and fragments were similar, and the initial fast loss from the interstitial fluid spaces in slices was avoided, so that efflux during the period of observation approximately obeyed first order kinetics. The following times, measured from the moment of the suspension of tissue in efflux medium, circumscribe the intervals chosen: for sodium, 1–2 min and 0–10 sec for slices and fragments respectively; for carbon-14, similarly, 5–25 min and 0–20 sec.

An increase in the rate of efflux of sodium of approximately ten-fold was observed in fragments compared with slices (see Table 1). A similar result was obtained in experiments in which the use of an isotonic solution of choline chloride provided for sodium the same high efflux gradient as for paramino hippurate. Among the possible reasons for the relatively high rate of efflux of sodium from fragments may be the shortening of the path of diffusion through the interstitial fluid compartment of slices and the setting free of the intercellular membranes<sup>7</sup>. The same factors should also modify rates of efflux for other solutes. A much larger acceleration of efflux was seen, however, especially in the case of paramino hippurate. This supports the view that efflux of this substance does occur largely across the luminal membrane. Presumably, the same applies to tetraethyl ammonium.

Table 1. EFFLUX RATES FROM SLICES AND FRAGMENTS OF RABBIT KIDNEY CORTX

Solute	Slices			Fragments		
	Mean	Range	No. of experiments	Mean	Range	No. of experiments
Sodium	0.36	0.09–0.73	16	3.4	3.1–3.8	6
PAH	0.016	0.002–0.020	11	0.94	0.74–1.30	7
TEA	0.016	0.003–0.027	5	0.41	0.25–0.71	7

Each experimental value represents the mean of five or more independent measurements.

If efflux of paramino hippurate from fragments does, as suggested, occur across the luminal membrane, then a high sensitivity to 'Benemid' of this efflux can be predicted on the basis of a recent analysis of the kinetics of the secretion of paramino hippurate *in vivo*<sup>8</sup>. This work led to the conclusion that 'Benemid' inhibits the transfer of this substance across both the peritubular and luminal membranes. In agreement with this we now find that 10<sup>-3</sup> molar 'Benemid' depresses efflux of paramino hippurate from fragments by 70 per cent. The fact that 'Benemid' so strongly inhibits this efflux argues against the likelihood that a large fraction of the efflux occurs across the intercellular membranes. It seems improbable that these membranes should possess specific carrier systems sensitive to 'Benemid'. The effect of 'Benemid' thus further supports the view that efflux of paramino hippurate from fragments is primarily a function of the luminal membrane.

Implicit in this view is the conclusion that because of the leak through the luminal membrane, fragments will not be able to accumulate paramino hippurate to the same high steady-state level as can slices. On the basis of experiments involving 2 h periods of incubation it has been claimed that accumulation of paramino hippurate by slices and fragments is equally high<sup>6</sup>. In our conditions the fragments, prepared by digestion with collagenase, invariably failed to yield the same high ratios of concentration of paramino hippurate in tissue as compared with medium. Thus, in five experiments, the following tissue: medium ratios were obtained after a 3 h period of incubation at 28° C in bicarbonate Ringer solutions, (0.08 mmolar paramino hippurate): for slices, 16 (a range of 12–24); for fragments, 7 (a range of 4–9). Relatively low final values of tissue: medium in a preparation of tubule have been reported<sup>9</sup>. All our observations therefore support the proposal that comparison of solute fluxes in slices and in suitably prepared renal tubular fragments can provide a measure of the properties of the luminal membrane.

### Comparison of DNA revealed by Feulgen and by Ultra-violet Light in Rabbit Spermatozoa after Storage in the Male Efferent Ducts

PUBLISHED data concerning the correlation of the content of DNA of spermatozoa and their capacity to fertilize are contradictory. We have therefore investigated thirteen sexually mature rabbits with normal spermatogenesis. Ejaculates were collected from all the rabbits, and the content of DNA in single spermatozoa (twenty on a slide) was measured in visible light at 560 mμ, after they had been stained with Feulgen by a standard technique, and in ultra-violet light at 260 mμ while still unstained. The measurements were made with an automatic scanning microspectrophotometer<sup>1</sup>. Testicular degeneration was induced in ten rabbits by means of a hot water spray on the scrotum (10' at 46° C). The three remaining rabbits served as controls. Both the controls and the treated animals were killed at different intervals after treatment and spermatozoa were collected from the caput epididymis, the cauda epididymis and the ampullae. In these spermatozoa, too, the contents of DNA were measured in twenty cells after staining with Feulgen, and in the ultra-violet spectrum.

The ejaculated spermatozoa collected before treatment showed a very variable content of DNA revealed by Feulgen in contrast to the constant values for DNA given in ultra-violet light. The mean value given by Feulgen was  $4.11 \pm 1.07$  with a coefficient of variation of 0.25, and the mean DNA value in ultra-violet light was  $5.18 \pm 0.08$ , and the coefficient of variation was 0.015 (Table 1). The same variability was found in different ejaculates from the same rabbits after staining with Feulgen (a mean value of

$4.52 \pm 0.95$ , and a coefficient of variation of 0.21), but the DNA in rabbits shown in ultra-violet light was constant (a mean value of  $5.21 \pm 0.11$  and a coefficient of variation of 0.02). Spermatozoa with normal or low DNA values shown by Feulgen, however, gave similar curves for hydrolysis.

Application of heat provoked severe testicular lesions but did not influence either the content of DNA shown by Feulgen or the content of DNA in ultra-violet light. In the spermatozoa, the mean value of DNA before and after treatment was not significantly different. After staining with Feulgen, however, there was great variability within and between rabbits; the mean value of DNA shown by Feulgen before treatment was  $4.06 \pm 1.06$  and the coefficient of variability was 0.26; after treatment the mean value was  $4.31 \pm 1.51$  and the coefficient was 0.35 (Table 1).

E, Ejaculate; CE, caput epididymis; C, cauda epididymis; A, ampullae.

The high coefficients of variation were mainly the result of a gradually decreasing content of DNA shown by Feulgen in the spermatozoa from the caput to the ampullae. The least significant difference<sup>2</sup> was 0.72; the DNA values given by Feulgen in the ampullae (3.41) were significantly lower than in the caput (5.00) and in the cauda (4.67). The differences between caput and corpus were not significant. The ejaculates yielded DNA values with Feulgen which were intermediate between those of the epididymis and those of the ampullae. For the DNA seen in ultra-violet light very constant results (mean value of  $5.18 \pm 0.05$  and a coefficient of variability of 0.01) were obtained at death and no correlation could be detected between this content of DNA and the site of collection (Table 1).

These experiments reveal an effect of ageing in the male efferent ducts. A similar trend has been demonstrated in

spermatozoa of bulls after ageing *in vitro*<sup>3,4</sup>. The basic mechanism for this decrease in DNA which stains with Feulgen when storage is carried out *in vivo* is not yet clear, but the constant values for DNA in ultra-violet light in all spermatozoa measured suggest that the DNA molecules show a decreased quantitative response to the Feulgen reagent during storage. Hydrolysis curves of the same shape for spermatozoa with normal or low DNA values would upset the hypothesis that DNA would become more sensitive to hydrolysis in normal hydrochloric acid at 60° C after storage *in vivo*, but this requires further confirmation. On the other hand the very stable DNA values in ultra-violet light, even in these spermatozoa with extremely low DNA values shown by Feulgen, suggest that the nucleotides are intact and that no hydrolysis has commenced during the storage processes in the male ducts.

This research was supported in part by an award from the Lalor Foundation, Wilmington, Delaware, U.S.A., to the senior author.

*Note added in proof.* Since this paper was submitted, Gledhill *et al.* have found testicular spermatozoa in the bull to have a higher Feulgen DNA content than epididymal spermatozoa (*Exp. Cell. Res.*, **41**, 652; 1966).

### Effects of Oestradiol on Calf Endometrial Tissue *in vitro*

CURRENT concepts of the mode of action of steroid hormones involve activation or inactivation of enzymes; alteration of the permeability of cellular or nuclear membranes; and activation or inactivation of the genome by gene derepression or repression<sup>1-3</sup>. More recent work with oestrogens appears to support the latter hypothesis. Among the reported biochemical effects, detectable only a few hours after hormone administration *in vivo*, are increased RNA (especially nuclear RNA) and protein biosynthesis, and increased activities of various enzymes, for example, RNA polymerase, enzymes which activate amino-acids and alkaline phosphatase<sup>4-6</sup>. These reactions occur relatively early, but they may be considered to be secondary to an undetected primary event.

A major problem of the use of rat uteri, the most common test object for biochemical investigations, has been the difficulty of clear-cut isolation of the endometrium in useful quantities. It was considered that unequivocal biochemical results could be obtained if specific target organs were available in large quantities. Several histochemical investigations have referred to the non-uniformity of the uterus, which would be expected to give rise to misleading biochemical data derived from the use of whole tissue extracts. With calf endometrium *in vitro* we have overcome these problems.

An essential prerequisite for investigation of isolated target tissues incubated with hormones is that the test

object should show a similarity of morphological and biochemical changes which are known to occur *in vivo*. In the past 15 years very few *in vitro* effects of oestrogens have been observed<sup>2</sup>, and the reports generally refer to whole rat uteri incubated for only a few hours. Our findings, however, support the idea that explants of endometrial tissue of the calf, maintained in tissue culture for up to 2 weeks, remain responsive to oestradiol when it is added to the incubation medium, and that they exhibit the same morphological and biochemical effects as are caused by the injected hormone.

The explants (2 mm × 2 mm; 0.02–0.15 mm thick), preserving the surface epithelium and the bulk of the lamina propria, were dissected from the middle portion of the opened uterine horns of freshly killed virgin heifers which were about 8 weeks old. Two tissue fragments were placed in Rose chambers under dialysis membranes and incubated at 37° C with 1.7 ml. of Eagle's basal medium containing 10 per cent foetal bovine serum free of oestradiol, 100 u/ml. of penicillin and 50 µg/ml. of streptomycin. The medium was replaced every second day except in chambers where low pH values suggested the need for more frequent feeding. After 6 days, the medium was exchanged for a medium containing  $1.2 \times 10^{-6}$  molar oestradiol-17 $\beta$ . No bacterial contamination was observed during incubation. When technical difficulties were encountered, they were thought to be caused in part by the hormonal status of the animals (for example, age, feeding, pretreatment with diethylstilboestrol) and partly by the incubation conditions (for example, the use of bovine serum with an unknown hormone content, or an unsuitable concentration of antibiotics). The explants were examined by time-lapse cinematography using Zeiss phase contrast optics (one or eight frames/min). The activity of alkaline phosphatase was demonstrated using Burstone's method for frozen tissue<sup>7</sup>.

Time-lapse cinematography of sections of the stratum compactum of intercaruncular areas revealed that the

Fig. 1. Frequency of mitoses before and after administration of oestradiol to explanted calf endometrial tissue, examined by time-lapse cinematography.

Fig. 2. (a) Calf endometrial tissue after 7 days *in vitro*. (b) Cells from the same culture chamber as (a) after 19 h of treatment with  $1.2 \times 10^{-6}$  molar oestradiol.

Fig. 3. (a) Untreated calf endometrial tissue after 8 days in culture. (b) Calf endometrial tissue after 46 h of treatment with  $1.2 \times 10^{-6}$  molar oestradiol.

first statistically significant burst of mitoses occurred about 40 h after the administration of hormone (Fig. 1). Regardless of the morphological difference, this is rather later than the 24 h reported for the appearance of numerous mitoses in the luminal and glandular epithelium of the rat uterus<sup>8</sup>. Occasional mitoses were noted after 20 h, however. Enlargement of the nuclei (two to threefold), nucleoli, and of the cells, which was probably caused by increased nuclear activities and imbibition of water respectively, was detected after about 19 h (Fig. 2), which agrees with the findings of Asdell *et al.*<sup>9</sup> after injection of oestrogen into ovariectomized heifers. Virtually no mitoses were observed during the 6 days before treatment with the hormone.

In a series of experiments with sections showing few indistinct glands of small diameter ( $20\mu$ ), the height of the glandular epithelial cells increased two to threefold after treatment with  $10^{-6}$  molar oestradiol for 24 h. These cells became columnar and contained ovoid, basal, vesicular nuclei and filamentous mitochondria. The numbers of glands increased significantly over a period of 46 h (Fig. 3). When the explants were incubated in the presence of solutions of oestradiol of decreasing molarities ( $1.2 \times 10^{-7}$ ,  $10^{-8}$ ,  $10^{-9}$  and  $10^{-10}$  molar),  $10^{-9}$  molar oestradiol appeared to be limiting for a definitive response; equivocal results were obtained with  $10^{-10}$  molar oestradiol.

Alkaline phosphatase activities were followed using explants incubated for 2 h, 4 h, 6 h and 18 h in Eagle's basal medium containing  $1.2 \times 10^{-6}$  molar oestradiol without the bovine serum. Some weak staining of the peripheral cells was noted, in particular where the lining epithelial cells were preserved, but increasing enzyme activities in the glandular epithelial cells compared with the controls were disclosed after 4 h of treatment and were at a maximum after 6 h and 18 h. No distinction could be made between the stainability of the basal, mid and neck gland portions.

The application of tissue culture techniques provides a refinement of biochemical investigations of uterine alkaline phosphatase of mice and rats<sup>8</sup>. These *in vitro* findings agree with *in vivo* reports by Sykes *et al.*<sup>10</sup>, but are somewhat inconsistent with Kenny's results<sup>11</sup>. This could be explained by the presence of different concentrations of progesterone.

Attempts were made to follow the effects of oestradiol on single cell cultures consisting predominantly of surface epithelial cells. These cells, obtained by the trypsin technique<sup>12</sup>, were viable and exhibited outgrowth for 8 days. No significant stimulatory or inhibitory effects caused by hormone concentrations ranging from  $1.2 \times 10^{-6}$  to  $5.8 \times 10^{-8}$  molar could be detected.

As far as we know, there have been no investigations of bovine endometrium in tissue culture which show a specific and pronounced morphological and biochemical sensitivity to administered oestradiol (ref. 13 and personal

communication from Biggers). As long as concentrations of natural hormone in the tissue and medium are carefully controlled, our results seem to recommend tissue cultures of hormone target organs as the experimental system; thus possible effects of the blood and nerve supply are eliminated.

## MICROBIOLOGY

### Mode of Action of Penicillin

A BIOCHEMICAL explanation for the antimicrobial activity of penicillin has been proposed<sup>1</sup>. In this hypothesis the structure of penicillin was related to that of intermediates known to be involved in the synthesis of cell wall material<sup>2</sup>. It was suggested that penicillin interferes with a transpeptidation reaction responsible for the cross-linking of mucopeptide chains in the cell wall polymer. The reaction is represented as follows:

The ability of penicillin to interfere with this reaction was attributed to its putative structural resemblance to the D-alanyl-D-alanine portion of the peptide chain.

We have used a similar approach to investigate the mode of action of penicillin, and are encouraged to report our findings in order to stimulate further experimentation and to prevent needless duplication.

Our approach was strictly enzymological, and deliberately ignored what was known of the biochemical steps in cell wall synthesis. We started with the assumption that penicillin was a potent competitive inhibitor of an enzyme that participated in some phase of cell wall synthesis. On the basis of experience with other enzymes<sup>3</sup>, the high activity of penicillin seemed to be caused by its rigidly constrained structure, part of which was in the same conformation as that of a vital

substrate when bound to the enzyme. In other words, we assumed that there were two parts to the penicillin molecule, one portion that mimicked the substrate and another that was responsible for maintaining the first in the proper conformation. The fact that the activity of penicillin is lost on hydrolysis of the amide bond of the  $\beta$ -lactam ring, as well as some other considerations, led us to the conclusion that the two parts of the molecule were as follows:

where - - - represents constraining bonds and — represents substrate bonds. The substrate analogue of penicillin *G* would therefore be phenacetylglucyl D-valine; that of penicillin *V* would be phenoxyacetylglucyl D-valine. These compounds as well as a number of closely related ones were synthesized and are listed in Table 1 with their melting points and specific rotations. All gave satisfactory elementary analyses.

Table 1. ACYLATED DIPEPTIDES\*

Compound	Melting point	Specific rotation $[\alpha]_D^{25}$

" " DL-alanine	124	— " " "

\* All the derivatives were prepared by acylation in the presence of excess aqueous bicarbonate of the free dipeptides which were synthesized by known procedures or purchased from Mann Research Laboratories, Inc., New York.

According to the hypothesis, the acylated glucyl D-valine or the related derivatives should show biological activity. For example, one might expect that they would have antimicrobial activity, but, because they are not structurally constrained, relatively high concentrations may be needed. On the other hand, they could antagonize the action of penicillin if they could be utilized by the target enzyme to make cell wall material. More recent findings<sup>3</sup> make the latter possibility unlikely, but when our work was carried out it could not be eliminated *a priori*.

Both of these possibilities were tested for all the compounds listed in Table 1. Three test organisms were used: penicillin-sensitive strains of *B. subtilis* (0.3 $\gamma$  penicillin/ml.) and *Staphylococcus aureus* (0.2 $\gamma$  penicillin/ml.) and a penicillin-resistant *Staphylococcus aureus* (200 $\gamma$  penicillin/ml.). Several experimental techniques were used: observation of growth in liquid media after a fixed period (22 h), nephelometric monitoring of liquid cultures throughout a 10 h period, and the use of disks impregnated with peptide. In the last case, the organism was seeded heavily on agar plates containing various concentrations of penicillin (including plates lacking the antibiotic) before the application of the disks. Antibacterial activity would have been indicated by the presence of a clear area around the disks if penicillin were absent from the medium. Neutralization of the action of penicillin would have caused the formation of a zone of growth around the disk implanted on a medium containing penicillin. With respect to experiments in liquid media, 20 per cent sucrose was present in order to prevent lysis of the organism<sup>4</sup> so that the action of penicillin could be a reversible one.

Concentrations as high as 2,000  $\gamma$ /ml. had no effect on growth of the test organisms nor was any interference

with the action of penicillin noted, even when borderline concentrations of the antibiotic were used. In accord with the hypothesis of Tipper and Strominger<sup>1</sup>, phenylacetyl D-alanyl-D-alanine was also synthesized (melting point 210° C;  $[\alpha]_D^{25} + 75.8$ ,  $c = 0.5$  in 1 per cent sodium bicarbonate) from D-alanyl-D-alanine<sup>5</sup>. It, too, possessed no biological activity in our test system at concentrations as high as  $4 \times 10^{-2}$  molar.

In view of our negative results, it was necessary to establish that our system and techniques were capable of revealing a competitive antagonism when it was known to exist. We therefore attempted to show reversal of the antibacterial action of D-cycloserine by D-alanine, as was done with mycobacteria<sup>6</sup>, *S. faecalis*<sup>7</sup> and with *Bedsoniae*<sup>8</sup>. A truly competitive reversal could be demonstrated over a range of concentrations of D-cycloserine at a ratio of D-alanine to the antibiotic of approximately 1:1 using our strain of *B. subtilis* as the test organism.

Despite the successful results with the D-cycloserine-D-alanine system, it is possible that whole cell preparations are unsatisfactory for the investigation of the activity of the acylated peptides. Perhaps sufficiently high concentrations of peptide cannot penetrate the intact cell. It must be noted that the uptake of penicillin is an irreversible process<sup>9</sup> and therefore not dependent on a high concentration gradient. Presumably, the binding of penicillin is followed by a chemical reaction leading to a covalent bond with the enzyme. Previous results<sup>10</sup> suggest that methicillin reacts with penicillinase in a similar manner. It would appear, then, that a final decision as to the validity of earlier suggestions<sup>1</sup> and of those outlined in this communication must await experiments with the proper cell-free systems.

### Salmonellin—a New Colicin-like Antibiotic

SALMONELLIN is a new colicin-like antibiotic characterized by its wide range of activity on the salmonellae and its failure to affect strains of *Escherichia coli*. Other *Salmonella* colicins have a much more restricted activity<sup>1,2</sup>. It is produced by a strain of *Salmonella eastbourne*, SC 11, from my collection of local isolates. During an investigation of about 2,000 strains of *Salmonella* for colicin-like activity, the new antibiotic was found only in this one strain. Using Fredericq's double layer technique<sup>3</sup> with the indicator organism, *Salmonella gallinarum*, which is useful in the detection of certain colicin-like reactions and bacteriophage, *Salmonella* SC 11 produced a very large, clear, ill-defined zone of inhibition. On nine strains of *E. coli*, including K 12 58/161 and phi (said to be sensitive to all colicins), SC 11 had no action.

On other sensitive salmonellae, SC 11 produced a characteristic large, double zone consisting of an inner clear area with a few colonies and an outer area with many colonies or reduced growth, often surrounded by a halo (Fig. 1). Strains sensitive to salmonellin (called sal-s), including a number of colicin producers, were found in Kauffmann-White groups, B, C, D, E, F, G, H, I, J, K, L, M, N, O, P, Q, R, S, T, V, and W for which the numbers of sensitive

and resistant strains are given in Table 1. Sal-s strains were also found in the Arizona group listed as *Salmonella* sub-genus III<sup>4</sup>.

Table 1 shows that some strains of *Salmonella*, including some colicin producers, were naturally resistant to salmonellin (designated sal-r) and sal-r strains of many sal-s salmonellae were obtained by picking colonies from their inhibition zones. It seemed possible that some of the naturally sal-r strains owed their resistance to production of salmonellin. They were, therefore, tested by the double layer technique, with fifteen different sal-s salmonellae as indicators. A few strains showed atypical zones on one or two indicators, but none resembled salmonellin either in range of activity or in appearance of the zone. SC 11 remained the only natural salmonellin producer (sal<sup>+</sup>) strain so far found.

The ability of SC 11 to transmit the sal factor to other sal<sup>-</sup> strains was indicated by the isolation of sal<sup>+</sup> forms of streptomycin resistant recipients of the *Salmonella*, Arizona and *Escherichia* groups from mixed broth cultures with SC 11. These sal<sup>+</sup> strains were distinguished from the donor, SC 11, not only by streptomycin resistance, but also by having the serological and biochemical characters of the recipient. They inhibited the characteristic wide range of salmonellae and showed the typical

inhibition zone of salmonellin. Two sal<sup>+</sup> strains, obtained from *E. coli*, still retained their full sensitivity to my salmonellae which produce colicin.

Salmonellin has not yet been detected in broth cultures, but it has been obtained in cell-free extracts of agar cultures. These extracts, though weak, retained activity after heating for at least one hour at 60° C or at least 20 min at 100° C. In agar cultures, *Salmonella* readily diffused through dialysis tubing and the large size of the inhibition zone suggested rapid diffusion in agar.

With certain strains of *Salmonella*, SC 11 showed bacteriophage action and was lysogenic for at least one type of bacteriophage, and, as plaque types suggest, probably more. The relation, if any, between salmonellin and bacteriophage activity is being investigated.

Among salmonellae, the salmonellin system provides two new markers, the sal factor (sal<sup>+</sup> or sal<sup>-</sup>) and the sensitivity factor (sal-s or sal-r). It also offers a number of other interesting possibilities for investigation of the relationship between Gram negative bacilli. Thus, transmission of the sal factor among various groups of Gram negative rods may uncover relationships not previously recognized. Furthermore, genetic exchange may be achieved, along with the sal factor, between genera that do not readily cross.

### Neuraminidase Activity of a Bovine Strain of Parainfluenza 3 Virus

In a discussion of the taxonomic implications of the term "myxovirus", it has been suggested that it is the property of myxophily and not morphology which establishes a true member of the myxovirus group of viruses. It was further suggested that some bovine strains of parainfluenza 3 (PI 3) virus lack the enzyme neuraminidase and that, because their relation with mucoprotein is limited to attachment (that is, they do not elute), they should not be considered as myxoviruses but rather as pseudomyxoviruses<sup>1</sup>. It has also been suggested elsewhere that bovine strains of PI 3 virus do not possess neuraminidase<sup>2</sup>. We have been unable to trace any published evidence to support these suggestions. During the course of an investigation into the role of PI 3 virus in the aetiology of bovine respiratory disease, one of us (P. S. D.) considered that both adsorption to and elution from guinea-pig erythrocytes occurred in the haemagglutination reaction with bovine strains of the virus. This is supported by other work<sup>3</sup>. The present report describes briefly some experiments made to test the neuraminidase activity of a bovine strain of PI 3 virus.

The T1 strain of bovine virus which we used was isolated from the tonsils of two calves<sup>4</sup>. The virus was grown in primary monolayers of calf kidney cells maintained in Earle's saline containing 0.5 per cent lactalbumin hydrolysate and 0.01 per cent yeast extract. The medium did not contain serum.

The cultures were collected 4 days after inoculation with the virus and, after freezing and thawing rapidly three times, they were clarified by light centrifugation. The virus suspension was then concentrated approximately thirty-fold by centrifugation at 105,000g for 60 min. The resulting concentrated viral suspension, used for the estimation of enzyme activity, had a haemagglutinating titre<sup>5</sup> of between 1 in 1,024 and 1 in 2,048/0.2 ml. Control preparations consisted of fluid collected from uninfected tissue cultures treated in a similar manner to the virus

Fig. 1. Appearance of a salmonellin zone of inhibition. The double layer technique was carried out on an agar plate.

Table 1. ACTIVITY OF NEURAMINIDASE IN TEST PREPARATIONS

Preparation	$\mu\text{g}$ of N-acetyl neuraminic acid liberated from bovine glycoproteins by 0.2 ml. of preparation in 2 h at 37° C	
	pH 5.8	pH 7.4
Bovine strain PI 3 virus	1.16	0.52
Control tissue culture fluid	0.07	0.02
Neuraminidase	24.5	17.3

suspension, and a commercially available preparation of neuraminidase (extract of *Vibrio cholerae*).

Serum from calves deprived of colostrum (globulin-free) and normal adult bovine serum were used as the source of glycoprotein substrate. The activity of neuraminidase was assayed by the incubation at 37° C for 2 h of 0.2 ml. of the test preparation, 0.2 ml. bovine serum (containing 180  $\mu\text{g}$  of total sialic acid<sup>6,7</sup>) and 0.1 ml. of a 0.2 molar phosphate buffer (final pH 5.8 or 7.4). After subjection to 100° C for 1 min to inactivate the enzyme, free sialic acid was estimated in the reaction mixture by a method<sup>8</sup> which was specific for N-acetylneuraminic acid. The results obtained with adult bovine serum as the substrate are shown in Table 1. Similar results were obtained when colostrum-deprived calf serum was used.

The suspension of PI 3 virus showed significant enzyme activity at pH 5.8 and 7.4. At pH 5.8, the optimal hydrogen ion concentration for viral neuraminidases<sup>9</sup>, the enzyme activity of the virus suspension was more than twice that observed at pH 7.4. The control preparation of neuraminidase, which has an optimal activity at pH 5.6 (ref. 10), also showed somewhat greater activity at pH 5.8 than at pH 7.4. The control, concentrated fluid collected from tissue culture, showed only very slight neuraminidase activity at either pH (Table 1).

These results show that T1 bovine strain of PI 3 virus possesses neuraminidase activity. If the criteria proposed<sup>1</sup> are accepted, then at least this bovine strain of virus should correctly be considered as a myxovirus.

### Failure of Function of the "Early Protein" induced by an Influenza Virus in Cells infected by Newcastle Disease Virus

AFTER infection of chick embryo cells with fowl plague virus (FPV), an influenza A virus, or with Newcastle disease virus (NDV), a para-influenza virus, "early proteins" are synthesized before viral RNA-synthesis starts<sup>1-4</sup>. These "early proteins" might function as an RNA-dependent RNA polymerase as has been demonstrated for picornaviruses<sup>5</sup>. In contrast to the picornaviruses, the "early proteins" of the myxoviruses are stable<sup>1-4</sup>. The purpose of this investigation was to determine whether or not the "early protein" induced by FPV is able to function for the multiplication of NDV.

The cell system and virus strains used and the procedure of infection have been published previously<sup>1</sup>. *p*-Fluorophenylalanine (FPA) has been used as an inhibitor for virus multiplication and the demonstration of the "early protein"<sup>1,2</sup>. If FPA is added to the tissue cultures immediately after infection, no viral RNA is synthesized.

The normal complement of viral RNA is produced, however, if the inhibitor is added 2 h post infection to FPV infected cells or 3 h post infection to NDV infected cells, respectively<sup>1,2,4</sup>.

In the present experiments chick embryo cells were infected with FPV and superinfected with NDV 2 h later. After the adsorption of NDV, 300  $\mu\text{g}/\text{ml}$ . FPA and 5  $\mu\text{g}/\text{ml}$ . actinomycin were added. Actinomycin prevents the synthesis of cellular and FPV-RNA, but not the synthesis of NDV-RNA<sup>6,7</sup>. Six hours after addition of the inhibitors 0.5  $\mu\text{C}$ . <sup>14</sup>C-uridine per culture were added and the radioactivity in the RNA was determined 2 h thereafter as described before<sup>8</sup>. The following controls were used: (1) FPA was omitted; (2) FPA was added 4 h after superinfection with NDV; (3) NDV and FPA were omitted; (4) tissue cultures alone were incubated with the isotope.

Table 1. SYNTHESIS OF NDV-RNA IN CELLS PRETREATED WITH FPV

FPV	NDV	Actino- mycin	Addition of FPA, time after superinfection	C.p.m. in RNA
-	-	-	-	17,000
+	-	-	-	199
+	+	+	0 h	110
+	+	+	4 h	1,470
+	+	+	-	1,041

Essentially the same results were obtained in four independent experiments. The results of one representative experiment are given in Table 1. It can be seen that the "early protein" of FPV is not able to stimulate the synthesis of RNA after superinfection with NDV if FPA and actinomycin are added immediately after superinfection. As already mentioned, actinomycin prevents the synthesis of cellular and FPV-RNA and, under the conditions used (addition of FPA immediately after superinfection), FPA interferes with the production of the "early protein" of NDV. Thus the "early protein" of FPV synthesized before FPA is added is not able to act as a substitute for the "early protein" of NDV. The control experiments show that the superinfected cells are able to synthesize NDV-RNA in the presence of actinomycin if FPA is either omitted or added after the "early protein" of NDV is already synthesized.

Two different possibilities might be considered to explain the fact that the "early protein" induced by FPV does not function in the NDV-system. It is known that the RNA of FPV is synthesized within the cell nucleus<sup>9</sup>, while NDV-RNA very probably replicates in the cytoplasm<sup>10</sup>. Thus the "early protein" of FPV might not be able to leave the nucleus. As shown with two different RNA-containing phages the RNA-dependent RNA polymerase (RNA replicase) is very specific in the sense that it uses only that RNA as template which has induced its synthesis<sup>11</sup>. A similar situation might apply to different myxoviruses.

These studies were supported by the Deutsche Forschungsgemeinschaft.

### *In vitro* Transformation of Cells of Hamster Brain by Adenovirus Type 12

THERE has been some investigation of the *in vitro* transformation of cultured mammalian cells by adenovirus type 12<sup>1-4</sup>. There is, however, only one report about the reproducibility of the phenomenon and the malignancy of the transformed cells. Transformed cells have never been examined for the presence of tumour antigen. A pathological investigation showed that the target cells of adenotumours were undifferentiated Schwann cells or mantle cells of the peripheral nervous system, which correspond to glial cells in the central nervous system<sup>5</sup>. We have observed earlier and more consistent transformation than has been reported previously, by the use of dispersed cells of the brain tissues of newborn hamsters. Preparation of the cells, the incidence of transformation and the biological characteristics of the transformed cells are described briefly in this communication.

Dissected brain tissues of several newborn hamsters were cut into pieces with scissors and incubated with serum containing modified Eagle's medium, at 37° C and left for 24 h. These incubated brain fragments were collected and digested with 0.01 per cent pronase P (preparation of protease from *Streptomyces griseus*), in Hanks physiological solution at 37° C for 30 min. The brain cells thus dispersed were cultured in square bottles for a week to obtain confluent growth of cells using the medium described above. The cells were dispersed in pronase and used as seed cultures for the transformation test: 1 ml. containing  $2 \times 10^5$  dispersed cells, suspended in the culture medium, was dispensed into each test-tube and incubated at 37° C for 2 days. The medium was then decanted and the virus stock fluid was immediately added to the culture. The virus stock fluid was prepared, by freezing and thawing, from a 7 day culture of adenovirus type 12 (Huie strain) and transferred serially to KB cell culture. The titre of the virus stock was  $10^{2.5}$  T.C.I.D.<sub>50</sub>/ml. when KB cells were used as the indicator cells. The cultures inoculated with virus were incubated for 1.5–48 h with the virus in the quantities shown in Table 1. After the adsorption of virus the cultures were fed again with the culture medium and incubated for about 2 months during which they were observed microscopically each day for the appearance of the transformed foci. Fig. 1 shows the appearance of the transformed foci. No foci were found in the control cultures into which virus was not inoculated. The first detection of transformed foci was 15–33 days after infection, which is earlier than that previously reported. The foci grew rapidly and reached a size of about 2 mm in diameter in about 15 days. This incidence of the transformation was not obtained if BHK21 hamster kidney cell line and the other embryonal hamster cell line (HE-32) were used.

The morphology of the transformed cells is quite distinct in that they are small epithelioid cells with large nuclei and a small basophilic cytoplasmic area. They had a tendency to aggregate and pile up. The more specific character of the transformed culture was that it grew

Fig. 1. Appearance of the transformed colony in culture of cells of newborn Syrian hamster, 34 days after inoculation with virus. Stained with Giemsa. ( $\times 210$ .) Note multilayered focus.

better in an atmosphere of 5 per cent carbon dioxide. The cells often failed to grow in the usual conditions of bottle culture, even with a large inoculum (20,000 cells/ml.) unrelated to the medium pH, but grew when 5 per cent carbon dioxide was supplied, even with a relatively small inoculum (500 cells/ml.). These characteristics were similar to those of the cells which were isolated from the tumour tissue induced *in vivo* by the virus and cultured serially *in vitro* and were not observed with KB and HeLa lines. Two cell lines obtained from two foci were similar in their tumorigenicity. Table 2 shows the result of the malignancy test expressed as the numbers of implanted cells sufficient to kill 50 per cent of the hamsters by development of tumours. Attempts to detect adenovirus in *in vitro* cultures of transformed cells were made in the following ways. (1) Transformed cells were cultured for several days in medium containing 2 per cent bovine serum and frozen and thawed three times. The supernatant was inoculated with the indicator culture of KB cells. (2) Transformed cells were mixed with KB and PS (pig kidney) cells and subcultured to observe the cytopathogenic effect induced by the virus. (3) The lysed cell supernatant was inoculated with the KB and PS cells. (4) Transformed cells were treated with 0.1–0.5  $\mu$ g/ml. of mitomycin C to induce adenovirus. (5) Electron microscopy of the transformed cells was carried out to detect any virus particles which were present. None of these methods has revealed virus in the transformed cells. The presence of tumour antigen<sup>6</sup>, however, was detected in the transformed cells as well as in the cultured tumour cells, with the use of the serum of a tumour-bearing hamster (Table 3).

Table 1. INCIDENCE OF TRANSFORMATION BY ADENOVIRUS TYPE 12 INOCULATION IN SYRIAN HAMSTER BRAIN CELLS *in vitro*

Experimental designation	Titre of inoculated (T.C.I.D. <sub>50</sub> /ml.)	Time for virus adsorption (h)	Medium used	Frequency of transformation (foci/test-tubes or bottles)
HB-1	Control (without virus)	—	MEM + 15 per cent bovine serum	0/3
	$10^{2.5}$	48	MEM + 15 per cent bovine serum	1/2
HB3-5	Control (without virus)	—	MEM + 10 per cent bovine serum	0/3
	$10^{2.5}$	24	MEM + 10 per cent bovine serum	5/3
HB-12	Control (without virus)	—	MEM + 5 per cent calf serum	0/6
	$10^{2.5}$	1.5	MEM + 5 per cent calf serum	0/3
	"	6	MEM + 5 per cent calf serum	2/3
	Control*	—	MEM + 5 per cent calf serum	0/2
	(without virus)	—	MEM + 5 per cent calf serum	2/2
	$10^{2.5}$	24	MEM + 5 per cent calf serum	0/2

Medium was Eagle's MEM (plus 0.03 per cent Bactopeptone, 110 mg of pyruvate and 10 mg of serine/l.) supplemented with serum. Cells were seeded with  $20 \times 10^4$  cells/test-tube and  $100 \times 10^4$  cells/bottle.

\* This experiment was performed with a culture bottle containing 5 ml. of medium.

AC*	0	0	0	0*
H-4 80T	4	4	4	0
AC	0	0	0	0
T-6	4	4	4	4
AC	0*	0	0	0

HT-2, *in vitro* transformed cells; H-4, tumour cells cultured serially *in vitro*; T-6, a hamster tumour caused by the inoculation of the virus. The titre of a serum of a tumour bearing hamster was 1:64 for T-6 tumour extract.

Anticomplementary effect.

These data strongly suggest that the observed event is malignant transformation *in vitro* by the adenovirus, such as polyoma virus and SV40 types, although it is still of lower incidence than transformation by the latter viruses.

The complement fixation test was made by Dr. H. Shimono, Japanese National Institute of Health. This work was supported in part by the grant-in-aid for Scientific Research from the Japanese Education Ministry.

## Role of Sialidase in the Initial Phase of Infection with Influenza Virus

THERE have been numerous investigations of the role of sialidase (neuraminidase), but definitive evidence of its functional significance is lacking: a result of technical problems and inadequate experimental designs<sup>1</sup>. It has been proposed that the enzyme is involved: (a) in the initial phase of the infectious process; (b) during intracellular multiplication; and (c) in the release of virion from host cells. Thus a specific sialidase inhibitor could conceivably be used to investigate directly the function of the enzyme in the infectious cycle of virus multiplication<sup>1</sup>. At present, appropriate inhibitors are not available<sup>2</sup>, but it seemed possible to evaluate (a) by an experimental approach which involved specific anti-sialidase antiserum, and by determination of its effect on the infectivity of A2/Japan 305/57 influenza virus in chick embryonated eggs.

For this purpose "purified" enzyme was prepared from Japan 305 virus and used for the immunization of rabbits for the production of anti-sialidase antiserum by methods previously reported<sup>3,4</sup>. Virus preparations were prepared,

assayed for haemagglutinins and egg infectivity (*E.I.D.*<sub>50</sub>) as described previously<sup>5,6</sup>. Enzyme analyses and enzyme inhibition assays were carried out in the same way as before<sup>3,4</sup>. The degree of inhibition of haemagglutination and of enzyme activity by rabbit anti-sialidase antisera is shown in Table 1. In addition, the antibody activities of two antisera, designated as AS544 and AS28, are also included. These were prepared with crude enzyme and virus preparations which had been treated with ether. It can be seen that antiserum AS544 and purified  $\gamma$ -globulin antiserum AS28 were reactive to both the enzyme and to the haemagglutinin. On the other hand, purified  $\gamma$ -globulin antisera AS19, AS23, AS26 and unfractionated antiserum ASR were reactive to the enzyme and were essentially unreactive to the haemagglutinin (< 1-10). This indicates that these four antisera are highly specific for the enzyme. It was found that antiserum prepared with enzymes which had been purified by gel filtration with 'Sephadex G-75' alone frequently inhibited haemagglutination<sup>3</sup>. Further purification of the enzyme obtained from 'Sephadex' columns by gel electrophoresis<sup>4</sup> allowed injection of rabbits with enzyme prepared in this way to give antisera which did not inhibit haemagglutination (see AS19, AS23 and AS26; Table 1).

Table 2 shows the effect of sialidase antisera on the *E.I.D.*<sub>50</sub> of Japan 305 virus. The non-specific antisera, AS544 and AS28, significantly neutralized the virus particles; whereas AS19, AS23, AS26 and ASR did not significantly neutralize the *E.I.D.*<sub>50</sub> of Japan 305 virus. Additional experiments were carried out to show that the lack of neutralization is not attributable to possible dissociation of virus and antibody complexes<sup>6</sup>. AS23 antiserum was added to serial ten-fold dilutions of virus and the mixtures of virus and serum were incubated at 37° C for 2 h and then at 0° C-5° C for 20 h. AS23 did not significantly neutralize the *E.I.D.*<sub>50</sub> of Japan 305 virus (*t* = 1.55) under these conditions of virus neutralization by antiserum; nor did AS23 diluted serially four-fold from 1-4 to 1-64 and added to a constant amount of virus (100 *E.I.D.*<sub>50</sub> dose) neutralize the virus. It is not possible to detect any enzyme activity at these dilutions of the virus.

Table 1. INHIBITION OF HAEMAGGLUTINATION AND SIALIDASE BY RABBIT ANTI-SIALIDASE ANTISERA

Rabbit serum No.	Titre causing inhibition of haemagglutinin	Enzyme inhibition Serum dilution*	Per cent
AS544	1-320	10 <sup>-1</sup>	90
AS28	1-320	10 <sup>-2</sup>	71
AS19	< 1-10	10 <sup>-2</sup>	91
AS23	< 1-10	10 <sup>-2</sup>	84
AS26	< 1-10	10 <sup>-1</sup>	87
ASR	< 1-10	10 <sup>-2</sup>	69

Assays of inhibition of haemagglutination and enzyme inhibition analyses were carried out as described previously<sup>3,4</sup>. AS544 and ASR were whole serum; the others were salt fractionated immune  $\gamma$ -globulin and further purified by chromatography on diethylaminoethyl cellulose column<sup>4</sup>. AS19, AS23, and AS26 were from rabbits immunized with enzyme initially purified on 'Sephadex G-75' column and then by polyacrylamide gel electrophoresis<sup>4</sup>.

\* The dilutions represent first serial ten-fold dilution which inhibited the enzyme reaction by less than 100 per cent.

Table 2. EFFECT OF ANTI-SIALIDASE ANTISERA ON THE EGG INFECTIVITY OF INFLUENZA A2/JAPAN 305/57

Experiment	Virus and antiserum*	<i>E.I.D.</i> <sub>50</sub> †	<i>t</i> ‡
(1)	Virus alone	7.50 ± 0.23	
	Virus and AS544	1.63 ± 0.32	14.00 + +
(2)	Virus alone	8.17 ± 0.23	
	Virus and AS28	2.50 ± 0.23	11.80 + +
(3)	Virus alone	8.57 ± 0.23	
	Virus and AS19	8.28 ± 0.23	0.81 n.s.
(4)	Virus alone	8.69 ± 0.41	
	Virus and AS23	7.83 ± 0.39	1.50 n.s.
(5)	Virus alone	7.50 ± 0.23	
	Virus and AS26	7.50 ± 0.45	0.00 n.s.
(6)	Virus alone	7.68 ± 0.40	
	Virus and ASR	7.50 ± 0.33	0.35 n.s.

One part of the antiserum was added to one part of serial ten-fold dilutions of Japan 305 virus. Virus-serum mixtures were allowed to react at room temperature for 30 min and then embryonated eggs of chick were challenged with 0.1 ml. of a combination of virus and serum.

\* Sera were assayed at 10<sup>-1</sup> dilutions.

† *E.I.D.*<sub>50</sub> expressed as log<sub>10</sub> ± standard error/ml.

‡ Student's *t* values calculated as follows:  $\frac{E.I.D._{50} - E.I.D._{50}}{\sqrt{((S.E._1)^2 + (S.E._2)^2)}}$  at infinite degrees of freedom; n.s., not significant; + +, highly significant.

These data indicate that the viral enzyme of influenza A, Japan 305, is not required for the initial phase of the infectious cycle of influenza virus in embryonated eggs. Virus multiplication occurred in the presence of adequate concentrations of specific anti-sialidase antibodies, which *in vitro* inhibited completely the enzyme present in virus particles diluted 1,000 or more times<sup>3</sup>. It has been reported that virus and antibody concentrations are directly related to enzyme activity and inhibition by antiserum<sup>2</sup>. The lack of effect of the antiserum to sialidase on the infectivity does not preclude the possible role of the viral enzyme during the intracellular phase of virus multiplication<sup>10,11</sup> or in the release of newly replicated virus from host cells<sup>12</sup>.

We reported previously that "purified" sialidase could be characterized by gel electrophoresis and immunoelectrophoresis, respectively<sup>4</sup>. The present data on enzyme inhibition, inhibition of haemagglutination, and *E.I.D.*<sub>50</sub> assays with mixtures of antibodies and specific antibodies show that these methods will be useful for further characterization of, in particular, the purity of influenza virus surface antigens. This is mainly because of the extreme sensitivity of the biological methods, inhibition of haemagglutination and assays of *E.I.D.*<sub>50</sub>.

These results further show that haemagglutinin and sialidase are distinct surface antigenic components of Japan 305 virus, which is in agreement with reported findings<sup>5,13</sup>. In addition, the lack of neutralization of the *E.I.D.*<sub>50</sub> of Japan 305 virus by sialidase antiserum supports the concept that (a) the haemagglutinin is responsible for the initial attachment of virus particles to host cells<sup>14</sup>; (b) sialidase is possibly involved during a phase of the infectious process of influenza virus in eggs after the initial phase<sup>10-12</sup>. Further work in this connexion is in progress.

## GENETICS

### Cytogenetic Studies of Two Species of Porpoise

THIS investigation was undertaken to compare the chromosomes of two species of porpoise, the Atlantic bottlenose (*Tursiops truncatus*) and the Pacific white-striped porpoise (*Lagenorhynchus obliquidens*), both small odontacete cetaceans of the family Delphinidae. The chromosome number and karyotypes were established for a male and female

*T. truncatus* and for two males and one female *L. obliquidens*.

The animals used in this study are members of the cetacean research colony, maintained at the Marine Biology Facility, U.S. Naval Missile Center, in California. The two species differ markedly in external appearance. *T. truncatus* dwells mostly in coastal or inshore waters, often swimming into bays and rivers<sup>1</sup>. They are common in the Atlantic Ocean along the East and Gulf coasts of the United States, as well as in the Mediterranean Sea and several other areas of the world. *L. obliquidens* ranges from Mexico to Alaska in the deeper offshore waters of the eastern Pacific ocean.

Blood samples were obtained by venipuncture of small vessels which run laterally down the centre of each side of the fluke. About 10 ml. of heparinized blood were withdrawn and refrigerated or kept at room temperature for periods not exceeding 2 h before a culture was set up. The microtechnique for culturing leucocytes from whole blood described by Arakaki and Sparkes<sup>2</sup> was modified slightly for use with porpoise blood. The type of medium used, duration of incubation of the cultures and the amount of phytohaemagglutinin (PHA) were varied to determine the optimal conditions for preparation of metaphase chromosomes. The samples from *L. obliquidens* were the easiest to obtain and to culture; almost every modification produced satisfactory preparations, while those from *T. truncatus* were of limited success. Table 1 summarizes these results. In general the chromosome preparations were inferior to those obtained from human blood, but were satisfactory for counting chromosomes and for establishing karyotypes for these mammals.

Table 1. SUMMARY OF RESULTS WITH VARIED TISSUE CULTURE CONDITIONS

Culture media	Culture results	
	<i>L. obliquidens</i>	<i>T. truncatus</i>
(1) Eagle's MEM (2 ml.) with: 20 per cent foetal calf serum, 0.2 ml. of whole blood and 0.01 ml. of PHA-P*	Good	Poor
(2) TC 199 (5 ml.) with: 20 per cent foetal calf serum, 0.7 ml. of leucocyte rich plasma and 0.2 ml. of PHA-M*	Good	Fair
(3) Eagle's MEM Spinner (5 ml.) with: 20 per cent foetal calf serum, 0.7 ml. of leucocyte rich plasma and 0.2 ml. of PHA-M*	Good	Good metaphases but few in number
(4) NCTC 109 (5 ml.) with: 20 per cent foetal calf serum, 0.7 ml. of leucocyte rich plasma and 0.2 ml. of PHA-M*	Very good	Poor

Incubation time: 3-4 days—acceptable results.

More than 4 days—clots formed and few metaphases seen.

Optimum conditions: *L. obliquidens*: NCTC 109 incubated for 3 days.

*T. truncatus*: Eagle's MEM Spinner incubated for 3 days.

\* 'Difco', as reconstituted.

Metaphases were accumulated by exposure to colchicine for 4 h. After incubation the cells were subjected to hypotonic treatment with 0.95 per cent sodium citrate, washed in methyl alcohol and glacial acetic acid fixative (3:1) mounted on slides by the air-dry method and stained with aceto-orcein. To establish a karyotype which could be regarded as representative, the chromosomes of several cells from each porpoise were counted, photographed and karyotyped. These results are summarized in Table 2 and the karyotypes are illustrated in Figs. 1 and 2.

The modal chromosome number is constant at forty-four for both species, male and female, and the chromosomes can be readily paired. There seemed to be sufficient diversity in size and morphology of the chromosomes to warrant an attempt to establish provisional karyotypes for these animals. Comparison of karyotypes between

Table 2. SUMMARY OF METAPHASE ANALYSES

Animal studied	No. of cells in which chromosomes were counted	No. of chromosomes/cell	No. of karyotypes
<i>Tursiops truncatus</i> , male	5	44	4
<i>Tursiops truncatus</i> , female	5	44	5
<i>Lagenorhynchus obliquidens</i> , male (A)	5	44	4
<i>Lagenorhynchus obliquidens</i> , male (B)	4	44	3
<i>Lagenorhynchus obliquidens</i> , female	8	44	4

individuals of the same and different species supported the establishment of a similar karyotype for both species.

The chromosomes are sub-classified into groups given designations of A, B, C, D, and the sex chromosomes (X, Y). Within the chromosome groups most of the individual pairs of chromosomes can be recognized and identified. Group A contains the first five pairs of large sub-metacentrics: the centromere of A-1 is more medial than A-2 although both pairs are about the same size; the centromere of A-3 is less medial than A-4 and is slightly larger; A-5 is the smallest of this group. The long arms of one A-2 chromosome seemed to be consistently longer than those of its paired chromosome. Group B comprises the smaller sub-metacentrics arranged in order of decreasing size. The centromere position is also characteristic in that it is: sub-medial in B-6; sub-terminal in B-7; sub-terminal in B-8; sub-medial in B-9; sub-terminal in B-10; sub-medial in B-11; and sub-medial in B-12.

Group C consists of four metacentric or very nearly metacentric pairs of chromosomes. C-13 is distinctly larger than the other three. C-14 to C-16 become progressively smaller; C-16 is slightly smaller than the last sub-metacentric, B-12. Group D is composed of acrocentric pairs; D-17 is considerably larger than any of the other pairs in group D. D-21 is the smallest of the autosomes. Because of the size of this pair in our preparations it was not possible to determine accurately whether

it was best grouped with the acrocentrics or sub-metacentrics, but as the smallest it was given the last of the autosomal designations.

The sex chromosomes are of the X,Y type, characteristic of mammals. The males have one X chromosome and one Y, the females two X chromosomes. The Y chromosome is the smallest of all the chromosomes. In two preparations it appeared to be sub-metacentric but generally the centromere was indistinct. The X chromosome is metacentric and intermediate in size between C-14 and C-15 and very nearly the size of B-11; the difference between the two is in the position of the centromere. In most of the cells examined, the X chromosome had arms which appeared more compact and rounded than those of any of the other chromosomes.

Using testicular squash preparations, Makino found a chromosome complement of forty-four in *Phocoenoides dallii*<sup>3</sup>. An accurate comparison between his spermatogonial chromosomes and the somatic cell metaphases of the present investigation is not possible, but he also found the Y chromosome to be the smallest and the X chromosome of medium size comparable with pair 10 or 11. Walen and Madin<sup>4</sup> investigated the chromosomes (prepared by tissue culture of kidney cells) of *Tursiops truncatus* (female) and pilot whale (*Globicephala scammonii*, male and female), and demonstrated a diploid (2n) chromosome number of forty-four for both species with the karyotype of *T. truncatus* in close agreement with our observations.

A diploid (2n) chromosome number of forty-four has been found for two species of porpoise, *Tursiops truncatus* and *Lagenorhynchus obliquidens*. Except for differences in sex chromosomes between male and female, there appear to be no obvious gross differences in chromosomal constitution between sexes in the same species nor between the two species (Figs. 1 and 2). Provisional karyotypes for male and female members of both species have been established.

This work was supported in part by grants from the U.S. National Science Foundation and the California State Department of Mental Hygiene. We thank Mrs. Iris Veomett for technical assistance, and David C. Renery for constructive criticism of the manuscript.

## ANATOMY

### Histochemical Demonstration of Melanocytes by the Use of 5,6-Diacetoxyindole as Substrate for Tyrosinase

The stages in the formation of melanin from tyrosine proposed by Raper<sup>1</sup> are generally accepted as the metabolic pathway of melanogenesis in mammalian pigment cells. Most of the stages have been examined in some detail by experimental systems *in vitro*, but the dehydrogenation of 5,6-dihydroxyindole by normal human melanocyte tyrosinase had not been established. It was considered that this could be determined by a comparison of the

Fig. 1. Representative karyotypes of male (top) and female (bottom) of porpoise species *T. truncatus*. The pairs of chromosomes have been numbered and grouped according to scheme outlined in text. The male and female seem to differ only in their sex chromosome make-up. The very small Y chromosome is paired with the X in the male.

Fig. 2. Representative karyotypes of male (top) and female (bottom) of porpoise species *L. obliquidens*. Comparison with the karyotypes of species *T. truncatus* in Fig. 1 shows no obvious gross differences.

distribution of reaction product in sections of normal skin incubated in appropriate conditions in solutions of dihydroxyphenylalanine (DOPA) and dihydroxyindole. It was, however, impossible to use the indole as a histochemical substrate because of the very rapid autoxidation which it undergoes. A substituted derivative, 5,6-diacetoxyindole, was supplied by Dr. R. J. S. Beer from material prepared synthetically<sup>2</sup>. This substance was suitable for use as a histochemical substrate after recrystallization from light petroleum.

The incubation medium was made from 0.1 per cent diacetoxyindole dissolved in ethylene glycol monoethyl ether (final concentration 3 per cent), made up with distilled water and with pH adjusted to 7.2 with solid sodium bicarbonate. Cryostat sections of normal human abdominal skin fixed with formol and calcium<sup>3</sup> were incubated in this medium for 3 h at 37° C. Control sections were incubated in a medium containing 0.1 per cent DOPA made up in the same way. These incubations were repeated subsequently with the inclusion of sections of skin from an albino subject and pigmented and depigmented skin from a patient with vitiligo. After incubation the sections were washed in distilled water and mounted in water-mounting medium for inspection.

Examination of the material showed that a black reaction product was present in cells situated in relation to the basal layer of the epidermis in the normal skin and in the material from a pigmented region of the skin of the patient with vitiligo. These results were comparable to those seen in the sections incubated in DOPA, and the DOPA-like distribution of the staining is shown in Fig. 1. No reaction product was observed in sections of albino or depigmented vitiligo skin.

These results suggest that the indole is enzymatically oxidized by tyrosinase. This conclusion is, however, questionable, for if there were an indole 5,6-acetyl esterase present in certain cells (for example melanocytes) it would, by hydrolysis of the substrate 5,6-diacetoxyindole, liberate 5,6-dihydroxyindole which could undergo spontaneous oxidation to the corresponding quinone, followed by polymerization to form melanin. For this reason sections of the normal skin giving the positive results described above were incubated in diacetoxyindole medium to which an azo dye had been added. This esterase incubation medium was prepared by the addition of 1 mg of hexazotized pararosaniline<sup>4</sup> to 10 ml. of indole solution made up as described. Control sections were incubated in medium which did not contain diacetoxyindole.

The result after 3 h of incubation at 37° C is shown in Fig. 2. Indole acetyl esterase activity was widespread in the cells of the epidermis and the distribution of reaction

Fig. 2. Normal human skin incubated in indole esterase medium. Reaction product is widely distributed in the epidermis in contrast to Fig. 1.

product was in marked contrast to the melanocyte staining in sections incubated with 5,6-diacetoxyindole alone.

It is, therefore, reasonable to deduce from these results that the enzymatic nature of the oxidation leading to the formation of indole 5,6-quinone is substantially confirmed, and it may be concluded in the absence of positive reactions in sections of albino and vitiligo skin that the oxidations of DOPA and dihydroxyindole are both brought about by tyrosinase.

I thank Dr. A. Jarrett for advice and Mr. A. Cane for technical assistance, and the Medical Research Council for a fellowship.

## BIOLOGY

### Leopard Frogs raised in Partially Controlled Conditions

THE difficulty of raising leopard frogs, *Rana pipiens*, to maturity in controlled conditions makes them impractical for many experiments<sup>1</sup>. Tadpoles have previously died soon after metamorphosis<sup>2</sup>, but we have now raised frogs to sexual maturity with a low mortality rate. Thus sibling adults can be used for experimental purposes, and using our methods (described here) it should be possible to carry out genetic studies over several generations and to develop partially inbred lines of these laboratory animals.

In April 1962, fertilized eggs from a pond in Springville, New York, were divided into several groups, each of which was put into an uncovered plastic pan, measuring 32 × 22 × 7 cm. The pans were half filled with pond water or well water. The animals grew and developed equally well in both types of water.

Fig. 1. Two generations of laboratory frogs. The first generation animals are 3 years old. The smaller animals, progeny of siblings of the older frogs, are 6 months old.

Dead eggs and embryos were removed as soon as they were identified. By stage 22 (prominent gills) the larvae were separated into groups of twenty to twenty-five, and were transferred to clean pans every second or third day. After each transfer, one or two pellets of Purina guinea-pig chow were added to each container. The tadpoles consumed the disintegrated pellets eagerly, and as they grew they were further separated until eventually five to ten were kept in each box.

The animals were transferred to polyethylene dishes measuring  $38 \times 33 \times 15$  cm when their front legs emerged. The pans were propped at an angle of  $10^\circ$ , and approximately 500 ml. of well water formed a pool at the lower end of each pan. The upper end of the pan provided dry space for feeding. The pans were covered with a metal screen lid.

The nutritional requirements of newly metamorphosed leopard frogs are unknown. In a preliminary experiment, the animals ate one or two small meal worms (*Tenebrio molitor*) at each thrice-weekly feeding. In a few months, however, the frogs died, often severely bloated, and this was not prevented by injections of B-complex vitamins. For this reason, the newly metamorphosed frogs were transferred to outdoor pens measuring  $4.5 \times 4 \times 2$  ft., with 0.25 in. mesh hardware cloth for the floor and sides, and chicken wire for the roof. The floor of each pen was covered with leaf mould to a depth of approximately 1 in. A shallow plastic pan with a sloping gravel floor and containing water was placed in the pen. Laboratory meal worms and an assortment of naturally occurring insects (mainly crickets and flies) were put into the pen daily. The animals were free to capture whatever other insects were available. In September the frogs were replaced in the dishes in the laboratory and maintained exclusively on a diet of meal worms. In succeeding summers, the meal worm diet was supplemented with flies and crickets. During the summer of 1963 the frogs were returned to the outdoor pens, but during the summers of 1964 and 1965 they were kept in the laboratory.

In November 1963, 19 months after the collection of the eggs, an attempt was made to obtain a second generation. Motile spermatozoa were observed in a suspension of minced testis from a representative male. Accordingly, 1  $\mu$  of 'Turttox' pituitary extract was injected into a female sibling to determine whether eggs could be obtained, but they could not be stripped from this female. In April 1964, a second female 24 months old was treated with the pituitaries of several frogs. This animal showed the increase in pigmentation and shedding of skin expected after such treatment, and eggs were obtained after 4 days, but they were misshapen and did not divide after exposure to motile spermatozoa from a sibling.

In December 1964, a third female, 33 months old, which had been treated with 1  $\mu$  of 'Turttox' pituitary suspension provided a small yield of apparently normal eggs. These eggs were fertilized with spermatozoa from a sibling male, and thirty apparently normal tadpoles developed,

eighteen of which metamorphosed into normal frogs (Fig. 1). To our knowledge, this is the only second generation of *Rana pipiens* produced in captivity.

We investigated the deficiency of the meal worm diet. Newly metamorphosed frogs in 1963 were divided into four groups. The first was fed meal worms alone; the second was given the varied diet of meal worms, flies, crickets and other wild insects; the third was fed meal worms which, on two occasions, were dipped in a suspension of adult frog faeces; and the fourth group was fed meal worms supplemented on three occasions by cod liver oil. The animals of the second group, which were given meal worms and insects during early life, were the only animals that showed satisfactory weight

gains and survival (Figs. 2 and 3).

The proteins of a sample of meal worms, a wild frog, and ten frogs deficient in nutrients were isolated by precipitation with trichloroacetic acid and washed with water, acetone and chloroform. The material was hydrolysed and the amino-acid content was determined. The glycine, lysine and cysteine content of the protein from meal worm was less than that of protein from frog, but the former contained all the measured amino-acids in moderate abundance (Table 1). There was no pronounced difference in amino-acid composition between the wild frog and the frogs on the diet of meal worms alone.

Our experiments do not identify the deficiency in the meal worm diet. The deficiency does not appear to be caused by a lack of amino-acids or fat soluble vitamins. If intestinal micro-organisms are required to produce some other growth factor, the organisms are not maintained in the frog gut but must be supplied frequently. Frogs fed on meal worms and two inocula of normal faeces failed to demonstrate nutritional competence.

Meal worms could possess some substance which is toxic to young frogs but tolerated by mature frogs. In our laboratory we have had no excess mortality in adult frogs maintained during the winter on meal worms alone. Furthermore, we have observed no ill effects in adult

Fig. 2. Weight gains of frogs fed on various diets. Each dot indicates gain or loss in weight of the surviving individual frogs between November 23 and December 14, 1963 (when supplements were no longer administered).

Fig. 3. Survival of frogs fed on various diets. The diets and numbers of animals in each group were as follows: —○—, meal worms alone (13); —□—, meal worms and cod liver oil (14); —△—, meal worms and adult faeces (15); —×—, meal worms and wild insects (9). Wild fertilized eggs were brought into the laboratory on April 27, 1963, metamorphosis into frogs was complete between July 2 and July 15. The experiment was terminated at the end of January 1964. All the frogs fed on wild insects survived until April 1964, when they were released.

wild frogs which were brought into the laboratory and fed on a diet consisting of meal worms alone. The deficiency of a meal worm diet appeared only in newly metamorphosed animals.

Table 1. AMINO-ACID CONTENT OF FROGS AND MEAL WORMS

Amino-acid	Abundance in protein sample (mole per cent)	Wild frog*	Deficient frog	Meal worm
Glutamic acid	13.1	12.1	11.3	11.3
Glycine	12.2	16.7	9.0	9.0
Aspartic acid	9.9	9.0	9.5	9.5
Alanine	8.4	8.4	9.3	9.3
Lysine	7.9	7.2	5.8	5.8
Leucine	7.6	6.9	8.0	8.0
Serine	5.8	5.6	5.6	5.6
Valine	5.4	5.1	8.9	8.9
Proline	5.4	6.2	5.3	5.3
Arginine	4.7	4.8	4.0	4.0
Threonine	4.7	4.4	4.6	4.6
Isoleucine	4.4	3.9	4.7	4.7
Phenylalanine	3.3	2.9	3.6	3.6
Tyrosine	2.4	2.2	6.0	6.0
Methionine	1.9	1.8	1.3	1.3
Histidine	1.9	1.5	2.4	2.4
Cysteine	1.0	1.1	0.7	0.7

\* A small amount of collagen-like protein was lost from this sample.

It seems likely that frogs can be more easily fed and maintained if the tadpoles are maintained at reduced temperatures. When our tadpoles were kept at approximately 24° C the time span from egg to metamorphosis of the first frog was 60 days. These tadpoles grew to about 5 cm before metamorphosis. In a later experiment, in which the water temperature was 17° C, the first frog developed in 110 days; these tadpoles grew to about 7 cm in length. The animals appeared to eat just as vigorously at the lower temperature as at the higher, and the frogs were larger at the time of metamorphosis.

It is now possible to raise frogs to maturity in a laboratory environment in spite of the difficulty of obtaining a completely controlled diet. Such frogs should provide better material for study than the captured wild animals now in use.

We thank Dr. Allen Grossberg for the amino-acid determinations.

## Transplantability and Life Span of Mammary Gland during Serial Transplantation in Mice

SMALL segments of mammary tissues obtained from a 358 day old virgin female *C57BL* mouse and from a 734 day old virgin female *CBA* mouse, when transplanted into genetically compatible mice, regenerated glands which appeared normal and which responded to either exogenous or endogenous hormonal stimulation in a manner similar to that of the mammary glands of the host, and secreted milk when the hosts nursed young<sup>1,2</sup>. The quiescent status of the mammary glands of old mice was attributed to their environment, particularly the hormonal status of the animal rather than to the ageing of mammary tissues themselves.

The present experiment was carried out to determine whether mammary tissues could survive for prolonged periods *in vivo* when environments are renewed repeatedly.

From the third mammary gland on the right side of a 135 day old female mouse of the *CBA* strain, segments of mammary duct, 0.6 mm in length, and a little surrounding adipose tissue, were transplanted into the fat pads from which the fourth mammary gland had been removed in young adult female host mice<sup>3</sup>. These were the  $T_1$  generation for serial transplantation. The hosts were hybrid mice (female *BCB* × male *CBA*, designated as  $BA_1$ ; and female *CBA* × male *BCB*, designated as  $BA_2$ ). Mammary gland tissues derived from the original donor were transplanted serially in  $BA_1$  hosts for six transplant generations ( $BA_1$  line) and in  $BA_2$  hosts for seven generations ( $BA_2$  line). Serial transplantations were made approximately every 3 months. Some host mice of  $BA_1$  and  $BA_2$  lines were not mated until after segments of these transplanted mammary glands had been transplanted to mice of the succeeding generations (virgin line). At the second transplantation-generation ( $T_2$ ) of both  $BA_1$  and  $BA_2$  lines, the hosts were mated soon after they received mammary grafts. After their first litters were weaned at 21 days *post partum*, they were not mated until they donated mammary tissues to mice of the succeeding generation. In this subline (parous line), the same procedures were repeated at each subsequent generation of serial transplantation. All the hosts carrying mammary transplants were allowed to rear litters as long as they were fertile and were kept until mammary tumours developed or their death seemed imminent.

The incidence of successful transplants is summarized in Table 1. The data concerning the incidence of tumours will be reported elsewhere. The transplantability of mammary tissues was comparable in all lines. The transplantability was not uniform in different generations. In  $BA_1$  line, the relative number of successful transplants declined to 4/38 in  $T_3$  of virgin line and to 1/34 in  $T_4$  of parous line. In  $BA_2$  line, a similar decline took place in  $T_5$  of virgin

Table 1. INCIDENCE OF SUCCESSFUL MAMMARY TRANSPLANTS AT DIFFERENT GENERATIONS OF SERIAL TRANSPLANTATION

Transplantation generation	Virgin line				Parous line

Total $T_2-T_7$	71	186	38.2	93	75	166	45.2	88
$T_1-T_7$	97	234	41.5	117				

line (3/40) and in  $T_4$  of parous line (3/36). During later generations the mammary grafts grew in relatively more hosts. The longest life span of mammary tissues of the original donor *CBA* mouse throughout seven generations of serial transplantation was 1,379 days (3 years and 9.5 months). This transplanted mammary segment had developed into a branched duct system that occupied the whole area of the fat pad without mammary gland of the  $BA_2$  host mouse in  $T_7$  virgin line when this host was killed at 812 days old. A few hyperplastic alveolar nodules had developed in this mammary gland. The transplanted mammary tissue was comparable with the mammary glands of the host.

Our experiment showed that selected and surviving mammary gland tissues can regenerate and grow the normal structures of mammary glands when placed in a younger animal. Whether the reduced transplantability of mammary tissues at three or four generations of serial transplantation was due to the lack of transplantability of the adjacent adipose tissue and connective tissues or of the mammary epithelium is not known. It has been claimed that white adipose tissue is not readily transplanted<sup>1,5,6</sup>. Mammary gland that had been maintained for 1,379 days and mammary gland in the seventh generation responded to endogenous hormonal stimulation in a manner similar to that of the mammary glands of the hosts. This could suggest the capability of mammary parenchymal tissue to survive *in vivo* indefinitely if the environmental conditions are favourable.

### Transplantability of Mammary Gland in Brown Fat Pads of Mice

THE importance of white adipose tissue as a stroma for the growth of transplanted mammary glands has been reported<sup>1-4</sup>. It has also been reported that interscapular brown fat tissues, which had been transplanted into mammary white fat pads in mice, sometimes survived and retained the characteristics of brown fat on transplantation and the mammary glands of the host could grow into them<sup>5</sup>.

Brown fat is morphologically, biochemically, physiologically and endocrinologically different from white fat<sup>6,7</sup>. Its physiological function is still obscure, but it has been reported to be closely related to endocrine function, particularly with ACTH, adrenocortical hormones, insulin, thyroid hormone and sex hormones.

Peripheral denervation of interscapular brown fat is followed by an increase in its content of water, glycogen

and lipids, and also by histological changes so that it comes to resemble white fat<sup>8-9</sup>. The concentration of 3-methylcholanthrene was found to be higher in interscapular brown fat pads than in mammary white fat pads when carcinogen, administered intraperitoneally, was recovered from these tissues spectrophotofluorometrically<sup>9</sup>. There are, however, apparently no reports of the regeneration and growth of mammary glands which have been isografted into intact or denervated interscapular brown fat pads in mice. Our experiment was undertaken to investigate interrelationships between mammary growth and stromal conditions.

Sixty-two segments of mammary duct, each 0.6 mm long, were obtained from the thoracic (third) pair of mammary glands of two female *CBA* mice by a "quantitative transplantation" method described previously<sup>3,4</sup>. With the aid of a dissecting microscope, single mammary transplants were inserted, using watchmakers' forceps, into the centre of each of the interscapular brown fat pads of the host mice. From a 4 month old donor *CBA* mouse, thirty-two segments of duct were transplanted into sixteen female *CBA* hosts 3 to 3.5 months old (Series I). The other thirty mammary segments obtained from a 3 month old female *CBA* mouse were transferred to fifteen female (female *CBA* × male *C57BL*) $F_1$  hybrid mice 1.5 months old (Series II). Immediately before mammary transplantation, the interscapular brown fat pads on one side of the host mice were peripherally denervated by a technique used by Sidman and Fawcett<sup>8</sup>; on the left side in Series I and on the right side in Series II. A sham operation was performed on the interscapular brown fat pads on the other side of the animals.

The host mice received injections of 1 mg of progesterone and one-third  $\mu$ g of oestradiol benzoate dissolved in 0.02 ml. of sesame oil daily for 3 weeks from the day after mammary transplantation. The site of injection was the dorsal subcutaneous area adjacent to the root of the tail to avoid local reaction to the transplantation sites caused by the injections. The host mice were killed on the day following the last injections. All interscapular brown fat pads were removed, fixed in 10 per cent buffered formol, sectioned serially after embedding in paraffin and stained with haematoxylin and eosin.

Mammary grafts survived transplantation equally well in both the denervated and sham-operated interscapular brown fat pads (Table 1). The denervated brown fat pads were larger and paler than the sham-operated pads on the opposite sides of the same host mice. The denervated brown fat was histologically different from the sham-operated fat. The fat droplets increased in size and decreased in number in the cytoplasm of denervated brown fat cells. Brown fat cells with multilocular features with the granular cytoplasm (Fig. 1) were often converted later to monolocular fat cells resembling in appearance those of white fat (Fig. 2). Sometimes the area adjacent to mammary grafts in sham-operated brown fat pads contained enlarged monolocular fat droplets (Fig. 3). It is not known whether or not these are surviving white fat tissues that had been transplanted together with segments of mammary duct. In either environment created by the different conditions of brown fat pads, transplanted mammary glands actively regenerated glandular structures, and responded to exogenous hormonal stimulation in a similar way (Figs. 1-3).

Table 1. RATES OF RECOVERY OF REGENERATING MAMMARY GRAFTS FROM EITHER SHAM-OPERATED OR PERIPHERALLY DENERVATED INTERSCAPULAR BROWN FAT PADS

Experimental group	Site of transplantation	
	Sham-operated brown fat pads	Denervated brown fat pads
Series I: female <i>CBA</i> donor to female host <i>CBA</i> mice	10/16* (62.5 per cent)	14/16 (87.5 per cent)
Series II: female <i>CBA</i> donor to female (female <i>CBA</i> × male <i>C57BL</i> ) $F_1$ hybrid host mice	13/15 (86.7 per cent)	12/15 (80.0 per cent)

\* Number of successful mammary grafts/number of mammary transplants. Differences in rates of recovery are not statistically significant.

Mammary glands of the axillary (second) or thoracic (third) pairs in mice usually do not grow into and occupy the whole bodies of brown fat pads that are apparently continuous with white fat surrounding those mammary glands. It has been reported that intervening structures, such as the fascial connective sheath between the fatty tissue and the mammary transplants, interfered with growth of transplanted mammary glands<sup>2,5</sup>. There seems to be, however, no fascial intervention between white fat of the second or third pairs of mammary glands and adjacent interscapular brown fat. It is, therefore, hard to explain this phenomenon which occurs in a physiological condition, because in both the previous<sup>6</sup> and the present experiments it was demonstrated that mammary gland tissues of the third pair and other pairs can survive on transplantation, regenerate and grow in brown fat tissues. Interrelationships between mammary growth and stromal conditions, particularly of adipose tissues, should be further explored.

This work was supported by a grant from the National Cancer Institute of Canada. I thank Miss Bette Element for technical assistance, and Dr. D. W. Fawcett of Harvard Medical School for instruction in peripheral denervation of the interscapular brown fat pads of mice.

### Influence of Multiple Anterior Pituitary Allografts on the Oestrous Cycle of the Syrian Hamster

TRANSPLANT studies of anterior pituitary tissue indicate that the hypothalamus exerts an inhibitory influence on the release of lactogenic hormone and that this hormone is luteotropic in the rat<sup>1</sup>. Comparable studies were undertaken as a preliminary investigation into the role of the pituitary in luteal maintenance in the hamster. Earlier studies indicate that autotransplants of anterior pituitary<sup>2,3</sup> (1-4 days *post coitum*) to the cheek pouch or the kidney capsule of the pregnant hamster do not supply enough lactogenic hormone to cause the corpora lutea to secrete progesterone in amounts sufficient for nidation. It was noted<sup>2</sup> that progesterone alone, in contrast with the rat<sup>4</sup> which requires oestrogen for nidation, can maintain blastocysts through nidation in the ovariectomized hamster. Similarly, our results indicate that more than one allograft of anterior pituitary to the cheek pouch is necessary to influence the oestrous cycle of the hamster.

The cheek pouch is used as the site of transplantation because of the simplicity of the technique and the peculiar properties of the pouch, which make it suitable<sup>5</sup>. Donors (adult male or female hamsters, *Mesocricetus auratus*) were decapitated under light ether anaesthesia. The anterior pituitary tissue was obtained by raising the cranium and removing the brain; the posterior pituitary was always discarded. Hosts were anaesthetized with sodium pentobarbital, a cheek pouch was everted and pinned on to a pine wood operating board and cleansed with an antiseptic solution. Both lobes of the anterior pituitary from a donor were inserted directly through a small incision in the cheek pouch epithelium, and the incision was closed with 5-0 catgut. The hosts received either male or female anterior pituitary tissue (one, four or six transplants/animal), and each transplant was inserted through a separate incision. Oestrous behaviour was checked daily with vasectomized or intact males from 3-5 h after the onset of darkness. Lighting was controlled to give a 12 h day. Both intact and hysterectomized females were used as hosts; sub-total hysterectomy (from the tubo-uterine junction to the cervico-vaginal junction) had been performed several weeks before transplantation.

Table 1 indicates the influence of a varying number of anterior pituitary allografts and the sex of the donors on the oestrous cycle of the hosts. The 4 day cyclic activity of hysterectomized hosts was completely unaffected by one anterior pituitary graft. Only one animal that received four or six grafts had normal cyclic activity; she was an intact host that had received six female grafts. Six allografts to the cheek pouch are probably necessary to influence the oestrous cycle of intact or hysterectom-

Figs. 1-3.

Table 1. INFLUENCE OF ANTERIOR PITUITARY ALLOGRAFTS ON THE OESTROUS CYCLE OF THE SYRIAN HAMSTER

Host	No. of hosts	No. of anterior pituitary and donor sex	Length of observation (days)	No. (%) incidence of cycles > 4 days	Dioestrous interval average (range) (days)
Intact	4	6 ♂	43-113	19 (50%)	8.7 (7-16)
"	3	6 ♀	43-114	8 (17%)	8.8 (7-9)
Hysterectomized	4	1 ♂	40-50	0 (0%)	0 (0)
"	4	4 ♂	43-45	5 (15%)	9.4 (8-13)
"	1	6 ♀	120	2 (8%)	11.0 (8, 14)
"	3	6 ♂	57-85	10 (56%)	17.7 (11-36)

ized females in a more or less consistent manner, that is, to prolong the dioestrous interval (8.7 and 17.7 days, respectively) to be comparable with that of pseudopregnancy in intact (10 days) or hysterectomized (18.5 days) females<sup>7</sup>. The onset of the first prolonged dioestrous interval occurred within 15 days (average) after transplantation. Although most of the donor groups were male, it is probable that allografts of male anterior pituitary are at least as effective as female anterior pituitary in causing prolonged dioestrous intervals.

We suggest that the occurrence of long cycles is due to the influence of lactogenic hormone from the transplants on the function of the corpora lutea and that lactogenic hormone is luteotropic in the hamster. Other work<sup>6</sup> suggested that exogenous prolactin (bovine) is also luteotropic in the hamster. The difference in the length of the long cycle between intact and hysterectomized females (with six grafts) suggests that the uterus has a controlling influence over the maintenance of the corpora lutea in the hamster. We have shown that uterine grafts may have a luteolytic activity since they tend to shorten the length of pseudopregnancy in the hysterectomized hamster<sup>7</sup>. Results from a recent investigation with hypophysectomized sows<sup>8</sup> suggest that the uterus has a direct luteolytic influence on the corpora lutea. The luteolytic influence of the uterus in the rat may, however, be mediated by the anterior pituitary, for autotransplants of this tissue can sustain luteal function for several months in the otherwise intact animal<sup>9</sup>.

When all transplants were removed from a host, oestrus occurred 1-3 days later; in each instance heat came sooner than would be expected if a single and brief release of lactogenic hormone in the intact animal could maintain corpora lutea of the hamster throughout a pseudopregnancy. Continued prolactin injection is necessary to maintain corpora lutea in the intact rat<sup>10</sup>. It is probable, therefore, that endogenous lactogenic hormone is released more than once or continuously to stimulate function of the corpora lutea during pseudopregnancy in the hamster.

Oestrus is recurrent in intact hosts, and so the luteotropic influence of the transplants is probably discontinuous. Similar observations have been made in rats<sup>1</sup> and mice<sup>11,12</sup>. It is possible that such grafts secrete lactogenic hormone discontinuously. This hypothesis is not attractive, for there is no known negative feedback mechanism that controls release of the hormone, and excess gonadotropins (human chorionic gonadotropin and pregnant mare serum)<sup>13</sup>, oestrogen and progesterone<sup>14</sup> all increase the content of lactogenic hormone in the serum of the rat over controls.

An alternative explanation is that corpora lutea become refractory to lactogenic hormone because of the luteolytic influence of the uterus. It is also possible that the uterus suppresses the release of lactogenic hormone from the intact pituitary and that there is a negative feedback relationship between the uterus and the hormone. Hysterectomy does not prolong luteal life indefinitely in the pseudopregnant hamster or the hamster and rat<sup>1</sup> with anterior pituitary transplants; there must also be a non-uterine source of luteolytic activity. Luteinizing hormone, for example, has been shown to have a luteolytic effect on "ageing" corpora lutea in the rat<sup>15</sup> and the rabbit<sup>16</sup>. We suggest that there may be a cyclic

activity of brain tissue (perhaps reticular formation)<sup>17</sup> which affects hypothalamic nuclei that produce factors which release follicle stimulating hormone and/or luteinizing hormone and the factor which inhibits lactogenic hormone. Cyclic changes have been shown in the endometrium and vagina of the hypophysectomized-ovariectomized-adrenalectomized rat<sup>18</sup>. There is no known explanation for these cyclic changes, but their existence allows for the possibility that brain tissue may have cyclic activity which affects phenomena of the oestrous cycle and that it can be exhibited in the absence of the pituitary, the ovaries, and the adrenal glands.

### Phase Dependent Changes of Circadian Frequency after Light Steps

DIURNAL rhythm has been shown in a great variety of species to be self sustaining, that is, under constant conditions of light and temperature the periodicity continues. The period length of the free running rhythm ( $\tau$ ) generally deviates from the exact 24 h cycle of the solar day; it is then called a "circadian" rhythm. The "circadian rule"<sup>1</sup> states that the period length of circadian rhythms in constant light is a function of the light intensity. The effect of light on the free running rhythm has been regarded as a parametric or proportional influence, that is, a continuous action of light on the biological oscillation<sup>1,2</sup>. This interpretation implies that the following period would not be affected by the position of the cycle at which the light intensity is altered.

Preliminary experiments with the beetle *Tenebrio molitor* showed that the organism responds to shifts from lower to higher light intensities according to the circadian rule<sup>3</sup>. But it was unexpectedly found that the time of the shift (relative to the circadian rhythm of the animal) had a definite influence on the magnitude of the period change ( $\Delta\tau$ ). Increases in light intensity from 0.01 to 2 lux and from 2 to 100 lux were used. The data were pooled, because the results were similar in both groups of experiments. Because different lengths of period had to be dealt with, the phase position in the cycle of the light steps is given in degrees (0°, onset of activity; 360°, full period).

Fig. 1 shows a periodic change of  $\Delta\tau$  as a function of the time of the shift. The magnitude of  $\Delta\tau$  is maximal when the increase in light intensity occurs 2-3 h after the

onset of activity; it is minimal about 12 h later. It is not clear from these results whether the curve reaches the zero line, that is, whether there is any phase in the circadian period where increasing light intensity causes no change in the period length. Although at the lowest part of the curve (at about 220°) the data show a large variance, there is a statistically significant difference between the mean of the high data in the range 322°–360° and 0°–75° and the mean of the low data in the range 75°–322° ( $P < 0.001$ ).

These results were, however, obtained from frequency measurements over an average of only 7.7 periods. This makes it difficult to determine whether the measured values are steady state frequencies or transients. There are two points in favour of the former possibility: (1) no real transients have ever been found in *Tenebrio*, as can be deduced, for example, from Fig. 5 of ref. 3 (this was confirmed by Prof. Aschoff's further examination of the original data). (2) A "transient slope" response curve dependent on phase is unlikely, especially as there is no correlation between phase shifts and the phase position of the cue (which might cause a phase dependent transient slope under certain conditions).

Changes in period length generated in a similar way have been described only by Harker<sup>4</sup> and Pittendrigh<sup>5</sup>. Pittendrigh describes phenomena which he calls "after-effects" and distinguishes between four kinds of immediate pretreatment which result in period changes: (1) the frequency of preceding entrainment; (2) the preceding constant light conditions; (3) preceding transients caused by light pulses (of 12 h duration); (4) preceding transients caused by a short period of entrainment. We have not found any dependence of these after-effects on phase.

Harker<sup>4</sup> investigated the dependence on phase of after-effects caused by short periods of entrainment. Cockroaches (*Blaberus*) were kept in constant darkness for 15 days. They were then subjected to a light-dark cycle of 12:12 h for 5 days, and then returned to complete darkness. The curve (Fig. 12, ref. 4) has a maximum positive value of  $\Delta\tau$  when the first onset of light was applied 4–7 h before the onset of activity; its maximum of negative changes occurs 4 h after the onset of activity. The changes, however, are small and do not exceed 15 min. Nearly half the data in Harker's figure have been derived from Roberts's experiments with *Leucophaea*<sup>6</sup>, and Roberts himself hesitates to interpret his data as conforming to the results obtained with *Blaberus*.

Period-response curves, such as that published (but not interpreted) by Harker and the curve described here, suggest a very different effect of light on the circadian mechanism from the parametric influence mentioned in the introduction. The degree to which the system is changed depends on the phase position of the cue. This kind of influence on the oscillating system can be called

differential, in contrast with the parametric influence already mentioned. Harker's curve is, to my knowledge, the first example of a phase-dependent differential effect of environmental conditions on the free running period.

Phase-dependent shift responses ( $\Delta\phi$ ) have been interpreted as a mechanism of entrainment, but phase-dependent period responses ( $\Delta\tau$ ) cannot be so easily explained in terms of their biological utility. Harker's results do not show conclusively which part of the light cycle (for example, dusk or dawn or the middle of one semi-period) applied the effective stimulus in her experiments. Harker takes the onset of light as the effective stimulus, but it could just as well be the termination; in this case the curve would have to be shifted by 180°. The curve might also be produced by a combination of light-on and light-off stimuli. This would explain the weak effect on  $\Delta\tau$  compared with the step-up effects on *Tenebrio*. It would furthermore explain the most striking difference between the response curves: whereas the "two direction" stimulus of Harker's and Roberts's light cycle elicits a "two directional" response curve in the cockroach (that is, produces positive and negative  $\Delta\tau$  values), the "one direction" stimulus of a light step results in a "one directional"  $\Delta\tau$  response curve in *Tenebrio*.

Not only is there an apparent similarity between step-ups in light intensity and light-on stimuli of a light-dark (LD) Zeitgeber, but there is also evidence that the step-up may function as a light-on stimulus in the experiments with *Tenebrio*. The normal phase relation of the activity rhythm of *Tenebrio* to a 12:12 h light-dark cycle is characterized by the onset of activity about 2 h before darkness begins<sup>3</sup>. In other words, the light-on stimulus of the light cycle occurs 10 h before or 14 h after the onset of activity. Fig. 1 shows that at this time (about 220°) the response to a step-up stimulus is least. If the  $\Delta\tau$ -response curve of *Tenebrio* is similarly shaped in LD, the light-on stimulus would coincide with the part of the curve in which practically no period changes are generated. Such a phase relationship between Zeitgeber and response curve would be expected because it promises stability. If the hypothesis is correct, it would suggest that the differentially caused changes in period length are somehow involved in the procedure of entrainment.

In conclusion, I would like to propose the term " $\Delta\tau$ -response curve" or "period-response curve" for results such as those shown here. The usual response curves should then be called " $\Delta\tau$ -response curves" or "shift-response curves" in order better to distinguish these two types of "phase-response curves".

Fig. 1. Changes of circadian frequency ( $\Delta\tau$  in minutes of ordinate) plotted as a function of the phase position of light steps from a lower to a higher intensity ( $\phi$  in degrees after onset of activity; onset = 0°/360°). Black circles indicate light steps from 0.01 to 2 lux, open circles 2 to 100 lux. High means with standard deviation including data between 322° and 75°; low mean including data between 75° and 322°. Statistical significance between high and low means:  $P < 0.001$ .

### Aseptic Rearing of *Aedes aegypti* Linn.

INVESTIGATIONS involving the use of *Aedes aegypti* mosquitoes reared under aseptic conditions have been chiefly concerned with the nutrition of the larva. Whereas published techniques<sup>1-5</sup> were satisfactory for small numbers of insects, they were found unsuitable when large numbers of pupae were required for tissue culture purposes. The method for producing bacteriologically sterile pupae described here has been in use for 2 years, and has been found convenient and simple.

*Aedes aegypti* eggs laid on filter paper were obtained from a laboratory colony and stored over saturated potassium chloride at room temperature until required. Batches of eggs on small (1 × 1 cm) pieces of paper were sterilized in a 2-in. glass Petri dish by immersion in 5 ml. of 10 per cent benzalkonium chloride for 40 min, followed by 80 per cent ethanol for 15 min and two rinses in sterile distilled water. The eggs and paper were transferred with aseptic precautions to a 40 ml. tube with 25 ml. sterile water; a loose-fitting cap was fitted and the eggs induced to hatch by reducing the pressure in a vacuum desiccator. Eggs less than 1 month old tended to hatch during sterilization, and eggs 1–2 months old were usually used.

Eight ounce culture bottles were prepared by adding about 1 g white bread to 80 ml. tap water or distilled water; the bottles were closed with a screw cap, autoclaved for 10 min at 10 lb. pressure and stored at room temperature. Before use, 20 ml. of a 5 per cent solution of 'Marmite', which had been passed through a Seitz filter and stored in 20 ml. portions in universal containers at room temperature, were added with penicillin (final concentration 100 u/ml.) and streptomycin (final 100 µg/ml.). Between 400 and 500 freshly hatched larvae were transferred to a bottle, the screw cap was replaced with a loose fitting 'Oxoid' metal cap and the whole incubated at 28° C. Loose caps were used, because anoxia occurred if more than 50 third or fourth instar larvae were confined in a bottle with a screw cap. Batches of larvae were split into further bottles as they grew; where possible all handling was under a sterile hood. Culture of fragments of larvae or medium inoculated on to blood-agar or nutrient-agar plates incubated aerobically remained sterile; occasional mould contamination (easily detected in the early stages by the "lumpy" appearance of the bread) was encountered. The use of mycostatin was found to be unsatisfactory; 100 u/ml. suppressed mould growth but slowed down larval development considerably, and even at 25 u/ml. pupae were fewer and smaller than when mycostatin was omitted. In practice, it was found more convenient to discard the occasional contaminated bottle.

Under these conditions, pupae formed in 10–12 days were comparable in size with those from a normal laboratory colony. For use, they were removed from the culture bottles with a sterile pipette and washed twice in sterile water.

### Synthesis of a New Amphidiploid Species of *Brassica*: *B. amarifolia* Narain and Prakash

THERE have been reports of the raising of artificial amphidiploid varieties of *Brassica juncea* Coss synthesized with members of different interfertile species of *Brassica* with twenty chromosomes as one of the parents and species of *B. nigra* Koch with sixteen chromosomes as the other parent<sup>1,2</sup>. Any attempt to cross *B. tournefortii* Gouan (also  $2n = 20$ ) with *B. nigra* has been unsuccessful<sup>3,4</sup>, and *B. tournefortii* does not give fertile hybrids with any of the *Brassica* species with twenty chromosomes<sup>4,5</sup>. Olsson has therefore assigned it a status as a separate species quite distinct from the other species of the genus with twenty chromosomes, which have been lumped under different subspecies of *B. campestris*<sup>5</sup>. We have also noted that there is very little homology between the A genomes

of *Brassica* and of *B. tournefortii* in their  $F_1$  hybrids, because twenty to sixteen univalents and nought to two bivalents were found in first metaphase plates and their genomes can be distinguished. An amphidiploid arising from the cross between *B. tournefortii* and *B. nigra* is therefore likely to be a new species combining good agronomic characteristics, dwarf size, profuse tillering habit, narrow flowering range and aphid resistance<sup>6</sup> of the wild donor parent, *B. tournefortii*.

With the foregoing objective in view, 4,000 flowers of *B. tournefortii* were crossed with *B. nigra* in 1962–63 and 1963–64. The seeds set fairly well and generally gave rise to matrophorphic plants. Only one seed was a genuine hybrid, of which the chromosomes doubled spontaneously early in its ontogeny. The new amphidiploid was fully fertile (86 per cent pod fertility), stable and true breeding for two generations. Meiosis was quite regular with eighteen bivalents in the first metaphase plate (Fig. 1). Its crossability with *B. juncea* was also very low; it gave no true hybrid with the latter. Details of the morphological characters of the amphidiploid are as follows.

The hybrid is a dwarf, erect (3–4 ft. high), branching annual, with a profuse tillering habit (Fig. 2). The stem is bloomed with a purplish tinge at the joints, and there

Fig. 1.

Fig. 2.

are many branches, which arise from the main stem at an angle of 50°. Leaves taste very bitter; the radical leaves form a rosette, and they are slightly petiolated, stiff and crisp, lyrate-pinnatisect, slightly lobed, with a serrate-dentate margin, sometimes sinuate, and hispid with white hairs. The lamina is uneven and dark green, and the terminal lobe is very large, forming about three quarters of the area of the leaf. The other lobes are smaller, and there are three or four of them. The main lobe is sparsely dotted with irregular protuberances on the upper surface. The cauline leaves are lyrate with a serrate-dentate margin, and are less hairy, while the upper leaves are lanceolate, entire and smooth. The inflorescence is a corymbose raceme. The flowers are bright yellow with petals separated by spaces. The anthers have introrse dehiscence. Pods are smooth and form an angle of 40°–50° with the main axis, are 5 cm long, with a beak of 7.5 mm, and are torulose. There are many seeds, seventeen to twenty-eight seeds/pod; they are brown with reticulation on the surface.

The amphidiploid looks suitable for direct cultivation. It has a narrow flowering range, gives a high yield, is resistant to aphids in field conditions and bears 30 per cent oil in the seed. It has been named *Brassica amari-folia* because the leaves taste very bitter.

## PATHOLOGY

### Atypical Reaction to Inhaled Silica

THE classical reaction of the lung to the deposition of air-borne silica is the formation of discrete nodules, which in man exhibit a characteristic disposition of dust and connective tissue fibres<sup>1,2</sup>. Although the experimental lesion does not reproduce all the human features<sup>3</sup>, I have confirmed that it remains focal and discrete<sup>4,5</sup>. In recent experiments on the disposal of inhaled particles within the lung parenchyma, specific pathogen-free (SPF) rats have been used in an attempt to eliminate the complication of pulmonary infection which not infrequently affects standard laboratory rats. The response of SPF rats differed greatly from that of the standard ones used in the earlier studies.

Some SPF rats inhaled Minusil quartz (particle size < 5 $\mu$ ) and others Dörentrup quartz (particle size < 3 $\mu$ ) for 600 and 1,200 h over periods of 6 and 12 weeks respectively. In the case of Minusil the mean atmospheric concentration of dust was approximately 40 mg/m<sup>3</sup> and with Dörentrup 30 mg/m<sup>3</sup>. Rats have so far survived for up to a year after exposure. Each pair of lungs contained a mean of 20 mg Minusil or 11 mg Dörentrup quartz (courtesy of Dr. A. Critchlow).

Grossly the lungs in both groups were large and collapsed only partially on removal. They showed extensive and irregular yellowish-white consolidation but no typical silicotic nodules. Histologically, fibrosis was limited to a few small areas of irregular outline and tended to be intra-alveolar; it was usually associated with a peripheral accumulation of foamy histiocytes, which often contained periodic acid-Schiff positive (diastase resistant)

granules and sometimes sudanophil fat. Fibrosis apparently started as an outgrowth from the walls of alveoli in which foamy macrophages had collected. Most of the remaining alveolar spaces were filled with eosinophilic granular material that also gave a positive periodic acid-Schiff reaction (diastase resistant). In this granular exudate birefringent particles of silica were identified in incinerated preparations. Rat lung thus consolidated bore a distinct resemblance to pulmonary alveolar proteinosis in man<sup>6</sup>, a similarity which was increased by the presence in the rat exudate of acicular birefringent crystals, occurring singly or in bundles. As survival increased after dust exposure, the granular material tended to diminish in amount, scattered macrophages and polymorphs appeared, and it may have been removed via the bronchial tree. The alveolar walls for the most part persisted apparently unchanged, but occasionally a further unusual feature was seen in the form of localized areas of epithelialization of alveolar walls resembling adenomatosis, the lining cells being cuboidal, columnar or ciliated. There was no evidence of pulmonary infection.

The nature of this exceptional response to quartz has yet to be elucidated, but the alveolar exudate seems to be derived from disintegrated cells, possibly macrophages, as in alveolar proteinosis<sup>6</sup>. The failure to develop typical fibrotic nodules in the presence of silica is striking, as is the feeble aggregation of the dust into foci and its prolonged retention in large areas of the parenchyma. The fibrogenicity of the two samples of quartz was established by intraperitoneal injection into standard and SPF rats. The widespread deposition and retention of a relatively large amount of quartz in a period of 6 to 12 weeks might lead to necrosis of macrophages as quickly as they are produced and in some way interfere with fibrogenesis. It is not yet possible to say whether the atypical reaction to quartz is related to the use of SPF rats.

### Effect of Chlordiazepoxide on Eosinopenia of Stress in Rabbits

CHLORDIAZEPOXIDE, a new psychotherapeutic drug, chemically unrelated to either phenothiazine derivatives or indole-alkaloid derivatives, has been reported to show a number of pharmacological activities<sup>1</sup>. A possible hypothalamic activity of chlordiazepoxide has been reported<sup>2</sup>. We have investigated the effect of this drug on a physiological activity controlled by the hypothalamus, that is, eosinopenia after emotional stress. The emotional stress was applied to rabbits weighing 1.5–2 kg by the method of O'Connor and Verney as adopted by Colfer *et al.*<sup>3</sup>. Blood samples were taken from the ear veins of rabbits once before and again 3.5 h after the emotional stress (electric shock) was administered. The strength of the stimulus given by an electronic stimulator was such that it produced signs of fright in the animal. A freshly prepared solution of chlordiazepoxide (50 mg/kg) was given intraperitoneally 0.5 h before the electric shock and by this time the animal was showing the tranquillizing effect of the drug. Electrical stimulus was not repeated for 2 days. After pretreatment with chlordiazepoxide the rabbits still showed signs of fright after a similar electric shock. The experiments were carried out on three rabbits, each animal acting as its own control. Average means of blood counts are as follows. Before administration of

drug and stimulus, total white blood cell count was 4,860/cm, and the total number of eosinophils was 486 (10 per cent)/cm. Total white blood cell count 3.5 h after electric shock was 6,187/cm (a rise of 28.5 per cent), and the total number of eosinophils was 309.35 (5 per cent)/cm (a significant fall). Total white blood cell count 3.5 h after administration of chlordiazepoxide and electric shock was 5,175/cm (a rise of 6.4 per cent), and the total number of eosinophils was 466/cm (8.25 per cent, no significant change).

When the experiments were repeated after 2 days, the blood counts before and after electric shock were found to be similar to those obtained in the control experiments. The eosinophils again registered a marked and significant fall; the eosinophil count before stimulation was 603 (9 per cent), whereas it was 268 (4 per cent) only 3.5 h after stimulation. The experiments were repeated three times on each rabbit.

The foregoing results show quite clearly that administration of chlordiazepoxide (50 mg/kg) given intraperitoneally 0.5 h before the electric shock effectively prevents the usual fall in eosinophil count that follows emotional stress in rabbits. In animals under stress with intact pituitary-adrenal mechanism adrenocorticotrophin (ACTH) is responsible for the production of eosinopenia by causing a liberation of 11-corticosteroids. The release of ACTH in such conditions of stress is again in the control of the hypothalamus. These experimental results, therefore, point towards a possibility of chlordiazepoxide acting on the hypothalamus and thereby preventing the liberation of ACTH induced by acute stress. There is, however, the possibility of the drug acting peripherally as well. The effects of chlordiazepoxide on eosinopenia after the administration of adrenocorticotrophin and cortisone in the same rabbits were studied. ACTH (2  $\mu$ ) was given intraperitoneally and cortisone (2 mg/kg) intramuscularly instead of electric shock as in the previous experiments. Chlordiazepoxide (50 mg/kg) was given intraperitoneally 0.5 h before either of the foregoing drugs. Results with ACTH were as follows. Before administration of ACTH and/or chlordiazepoxide the total white blood cell count was 4,937/cm, and the total number of eosinophils was 543 (11 per cent)/cm. Total white blood cell count 3.5 h after administration of 2  $\mu$  of ACTH was 8,000/cm, and the total number of eosinophils was 320 (4 per cent)/cm. Total white blood cell count 3.5 h after chlordiazepoxide (50 mg/kg given intraperitoneally) and 2  $\mu$  of ACTH given intramuscularly was 4,600/cm, while the total number of eosinophils was 506 (11 per cent)/cm. These results show that while ACTH itself caused a marked eosinopenia, ACTH given after premedication with chlordiazepoxide failed totally to produce eosinopenia.

With cortisone, results were as follows. The total white blood cell count before cortisone and/or chlordiazepoxide was 4,950/cm and the total number of eosinophils was 445 (9 per cent)/cm. The total white blood cell count 3.5 h after cortisone (2 mg/kg given intramuscularly) was 7,750/cm, and the total number of eosinophils was 155 (2 per cent)/cm. The total white blood cell count 3.5 h after chlordiazepoxide and cortisone was 7,100/cm, and there were no eosinophils. Cortisone (2 mg/kg) caused a marked eosinopenia in the rabbit. Whereas in the control count eosinophils formed 9 per cent of the total white blood cell count 3.5 h after administration of cortisone, eosinophils accounted for 2 per cent only. The most interesting finding is that chlordiazepoxide could not prevent the eosinopenia caused by cortisone. Moreover, while ACTH alone caused a large rise in the total white blood cell count (8,000 as against 4,937 in controls), the total white blood cell count was only 4,600 when ACTH was administered 0.5 h after chlordiazepoxide.

Premedication with chlordiazepoxide prevented eosinopenia of emotional stress (fright caused by electric shock); chlordiazepoxide similarly prevented eosinopenia after

the administration of ACTH itself, and chlordiazepoxide completely failed to prevent eosinopenia following the administration of cortisone. The foregoing results, therefore, suggest that in preventing eosinopenia of emotional stress in rabbits, chlordiazepoxide acted in some way against ACTH itself, but the mechanisms are not clear from the present experiments.

### Induction of Dental Caries in Gnotobiotic Rats by Streptococci of Human Origin

ORLAND *et al.*<sup>1</sup> have shown that an enterococcus isolated from conventional rats with dental caries could induce caries when it was used to infect germfree rats receiving a diet rich in sugar. Fitzgerald *et al.*<sup>2</sup> later obtained similar results with a previously undescribed anaerobic streptococcus (Strain FA-1), and Fitzgerald and Keyes<sup>3</sup> described the induction of caries in a conventional strain of albino hamsters with still another strain of anaerobic streptococcus (Strain HS-1). Zinner *et al.*<sup>4</sup> isolated streptococci, designated AHT, from human caries. These streptococci could induce caries in hamsters. These human streptococcal strains were identical morphologically, antigenically and in biochemical fermentation patterns to the hamster (HS-1) types. The present communication reports the isolation from human caries lesions of streptococci which cause caries in gnotobiotic rats.

The streptococcus was isolated from human carious debris by the fluorescent antibody method<sup>5</sup> using rabbit antisera prepared against the rat cariogenic streptococcal strain FA-1 (ref. 2). This human streptococcus (Strain BHT) was identical to the rat strain morphologically, antigenically and in its response to the various biochemical tests used for its classification. Like the rat strain, it conforms to none of the currently named species of streptococci.

The results reported are based on two separate experiments using young germfree rats of the National Institutes of Health Sprague-Dawley line. In the first experiment thirteen animals 38 days old were infected orally with cotton swabs. The swabs were soaked in a culture of strain BHT. They were maintained in sterile isolators for 90 days with coarse particle cariogenic diet 585-V (ref. 6), which contains 25 per cent sucrose, available *ad libitum*. The diet was sterilized by 4 Mrads radiation in a Van der Graff accelerator.

In the second experiment nine germfree rats were similarly infected with a substrain of BHT isolated from the animals of the first experiment. They were 35 days old at the time of infection and were maintained on a fine particle cariogenic diet 2000 V (ref. 7) which contains 56 per cent sucrose. This diet was available *ad libitum* and was also sterilized by irradiation.

Ten of the thirteen animals in the first experiment showed decay of one or more molar teeth. Twelve teeth were carious, eight lesions involved the enamel only, while four had penetrated into the underlying dentine.

In the second experiment eight of the nine animals were affected. Caries was found in twenty-four molars with twenty-one lesions confined to the enamel and three involving the dentine. Thus, by the application of the fluorescent antibody technique it has been possible to

identify and isolate certain streptococci from human caries which are identical morphologically, antigenically and in their biochemical characteristics with streptococcal strains known to be pathodontic for hamsters or rats. These streptococcal strains of human origin have been found to induce caries in hamsters or germfree rats, and also showed an immunological relationship with the organisms originally isolated from these animals.

The results indicate that some strains of streptococci may be found among the micro-organisms present in human dental caries which can induce caries in experimental animals. The possible significance of such organisms in the aetiology of human dental caries is now under investigation.

This investigation was supported by a grant from the U.S. National Institute of Dental Research, and a contract with the U.S. Public Health Service.

## IMMUNOLOGY

### Protective Action of Oestrogen against the Lethal Effect of Endotoxin in the Rat

DURING investigations on the vascular effects of endotoxin in the isolated rat liver<sup>1</sup>, it was noted that the vasoconstrictive response to the administration of bacterial lipopolysaccharide failed to occur if pooled female rather than male rat blood was used as the perfusate, and this prompted an investigation of the value of an oestrogenic compound in prolonging the survival time of rats after the administration of endotoxin. Female albino rats weighing 200–250 g, and male Sprague-Dawley rats weighing 350–400 g, were used. The animals were paired by sex and weight, and each pair was allotted to the treated or control group. Food and water were given freely until the start of the experiment, when they were removed. Conjugated equine oestrogens, expressed as sodium oestrone sulphate, were given intraperitoneally and each rat received 4 mg dissolved in 1 ml. of diluent at various intervals before and after the intraperitoneal administration of purified lipopolysaccharide (*E. coli* 0127:B8, Difco Laboratories, Detroit). The diluent was given at the same intervals to the control animals. The numbers of survivors in the treated and untreated groups were recorded at 18 and 24 h. The few deaths occurring after 24 h were not included in the results, and statistical significance was determined by the method of  $\chi^2$  using Yates correction.

A marked and significant protection of the animals was observed when the oestrogen was given 30 min and 1 h before the endotoxin (Table 1). In addition, the protection was almost statistically significant when given 15 min before the lipopolysaccharide. This protection applied to both male and female rats, but if the oestrogen and endotoxin were administered in the same syringe or the oestrogen was administered after the endotoxin, the animals were not protected. The action of these conjugated oestrogens appears to be short-lived, since no effect was observed if the pre-treatment was given at 2, 4 or 8 h. While the effect of adrenal cortical steroids in protecting against endotoxin is well known, no such action has been previously attributed to oestrogen. The intraperitoneal administration of 10 mg of cortisol 0.5 h before administration of endotoxin in rats has produced a significant increase in survival rate while the same steroid dose given 8 h before or 1 h after the lipopolysaccharide gave no protection<sup>2</sup>.

Table 1. THE RELATIONSHIP OF SURVIVAL TO THE INTERVAL BETWEEN ADMINISTRATION OF OESTROGEN AND ENDOTOXIN

Initial injection	Interval (h)	Endotoxin dose (mg)	Sex	No. of rats	Survivors at 18 h	Survivors at 24 h
Oestrogen	8	2	♀	10	4	2
Control (diluent)	8	2	♀	10	6	3
Oestrogen	4	3	♀	10	3	3
Control (diluent)	4	3	♀	10	3	3
Oestrogen	2	3	♀	10	3	1
Control (diluent)	2	3	♀	10	6	2
Oestrogen	1	3	♀	10	10	10
Control (diluent)	1	3	♀	10	4	4
0.02 > P > 0.01 0.02 > P > 0.01						
Oestrogen	1	3	♂	10	8	6
Control (diluent)	1	3	♂	10	3	2
Oestrogen	0.5	3	♂	10	9	9
Control (diluent)	0.5	3	♂	10	2	2
0.01 > P 0.01 > P						
Oestrogen	0.25	2	♀	10	10	9
Control (diluent)	0.25	2	♀	10	7	5
Oestrogen	0	3	♀	10	1	1
Control (diluent)	0	3	♀	10	1	1
Oestrogen	-1	3	♀	20	8	6
Control (diluent)	-1	3	♀	20	7	7

The mechanism by which these water soluble oestrogens provide protection is not clear. The similarity between their action and that of cortisol raises the possibility of mediation through the adrenal cortex. In man, ethinyl-oestradiol produces a prompt increase in free plasma hydrocortisone<sup>3</sup>, but these increased levels are in a physiological range, and not at the pharmacological levels necessary for such endotoxin protection. Oestrogens have been shown to be reticuloendothelial stimulants of a high order<sup>4</sup>, and endotoxin is inactivated by the reticuloendothelial system. The stimulatory effect of these hormones persists, however, for a prolonged period<sup>5</sup>, and since no protection against endotoxin toxicity could be demonstrated at 2 h or more, stimulation of the reticuloendothelial system would seem an unlikely mechanism. The effect of oestrogen appears to be a direct and immediate one, similar to the action of corticosteroids.

If oestrogens indeed offer the same protection as corticosteroids against endotoxaemia, their use might have a theoretical advantage over the adrenal hormones. There is good evidence that cortisone depresses reticuloendothelial function and lowers resistance to infection<sup>6</sup>, despite its protective effect against the lipopolysaccharides of Gram negative bacteria. Nicol and his colleagues, however, have demonstrated to the contrary that the oestrogen stimulates the body defences against a wide spectrum of infectious organisms<sup>7</sup>. Further work is in progress to investigate the protective effect of female

hormones against endotoxin in other species, and in various states possibly related to endotoxaemia.

## BIOCHEMISTRY

### Inhibition of Rat Liver Esterases by Organophosphorus Compounds

THE complex family of non-specific carboxylic esterases has been subdivided into different groups, principally on the basis of the results of inhibitor and activator studies<sup>1</sup>. One of the most important substances for this purpose is *E*600 (diethyl-*p*-nitrophenyl phosphate), which has been used extensively—both biochemically and histochemically—to distinguish between the *A* and *C* esterases, which are resistant to organophosphate and unaffected by concentrations of less than  $10^{-3}$  molar *E*600, and the *B* esterases, which are sensitive to organophosphate and are completely inhibited by  $10^{-5}$  molar *E*600 (ref. 2). In a histochemical study of indoxylesterases in rat kidney and other tissues, Hess and Pearce<sup>3</sup> found that 'Mipafox' (*N,N'*-di-isopropyl phosphorodiamidic fluoride) at a concentration of  $10^{-3}$  moles/l. gave a complete inhibition of *B* esterases similar to that obtained with  $10^{-5}$  molar *E*600, allowing the subsequent demonstration of *A* and *C* esterases. In other tissues<sup>4</sup>, however, it has been found that under histochemical conditions a much higher concentration of *E*600 than  $10^{-5}$  moles/l. is required to produce an inhibition comparable with that of  $10^{-3}$  molar 'Mipafox'. Increasing concentrations of organophosphate have a progressive inhibiting effect histochemically, which makes it difficult to distinguish clearly between organophosphate-sensitive and organophosphate-resistant enzyme species in terms corresponding to those of biochemical studies.

Some insight into the relative effects of the two organophosphate inhibitors has been gained from electrophoretic studies of liver homogenates using the technique of Smithies<sup>5</sup>. The starch slabs were submitted to a naphthol *AS* technique for the demonstration of esterase activity, using naphthol *AS* acetate as substrate (0.25 mg/ml. in phosphate buffer pH 7.3 incorporating 3 per cent propylene glycol) and fast blue *BB* (1 mg/ml.) as diazonium salt; incubation was carried out for 1 h at 37° C. Before exposure to the substrate mixture some slabs were treated with varying concentrations of either *E*600 or 'Mipafox' for 30 min at 37° C.

Two regions of the zymograms (labelled 1 and 2 in Fig. 1) are resistant to treatment with  $10^{-5}$  molar *E*600 (compare with the results of Eränkő *et al.*<sup>6</sup> and Niemi *et al.*<sup>7</sup>). Increasing the concentration of *E*600 produces a progressive inhibition within regions 1 and 2, and only the bands in region 1 survive treatment with  $10^{-4}$  molar *E*600. After exposure to  $2 \times 10^{-4}$  molar 'Mipafox' there are again the two regions of persistent activity, with region 1 much more markedly inhibited than region 2. Increasing the concentration of 'Mipafox' to  $10^{-3}$  molar completely abolishes the activity in regions 1 and 2, except for one strongly persistent band in region 2.

It appears, therefore, that there are two regions of organophosphate-resistant naphthol *AS* esterase in zymo-

grams of liver homogenates; one of these is particularly resistant to 'Mipafox' and is more readily inhibited by *E*600, while the other is resistant to *E*600 and more readily inhibited by 'Mipafox'. It might be expected, therefore, that the relative effects of the two inhibitors when used histochemically will vary from one tissue to another, depending on the local proportions of different enzyme species. If enzymes of similar character to those represented by region 1 predominate, 'Mipafox' would be expected to have a much stronger inhibitory effect on the total histochemical reaction than *E*600. Conversely, if enzymes of similar character to those represented by region 2 predominate, *E*600 would be expected to have a much more marked effect. It is possible that the histochemical use of both these inhibitors may permit a more precise identification of individual esterase species than can be attained by using one of them alone.

It is necessary, however, to make some reservations. In the first place, it is likely that the esterases which can be demonstrated histochemically are not identical with those shown in electrophoretograms<sup>6</sup>; the effects of organophosphate inhibitors may therefore be different in the two situations. Second, a paradoxical finding must be recorded, in that the difference between the effects of 'Mipafox' and *E*600 which has been described above for the naphthol *AS* technique, and which was repeated on several occasions with several animals, does not occur when naphthyl acetate is employed as substrate. Here (Fig. 1) *E*600 produces much less effect in region 2 and much more effect in region 1 than occurs with the naphthol *AS* substrate. The most strongly persistent band of

Fig. 1. The zymograms on the left are naphthol *AS* preparations, and show the effects of varying concentrations of 'Mipafox' (*M*) and *E*600 (*E*) compared with the uninhibited control (*C*). Organophosphate-resistant enzymes occur in regions 1 and 2. The two zymograms on the right, showing naphthyl acetate-esterase activity, illustrate the effect of  $10^{-4}$  molar *E*600. (The naphthol *AS* and naphthyl acetate preparations are from different animals; in each case the slots were overfilled (0.05 ml.) so as to provide a stronger residual pattern after inhibition.)

activity appears to correspond with the 'Mipafox' resistant band of the naphthol AS zymograms.

### Specific Inhibition of Gluconeogenesis by Biguanides

POSSIBLE schemes for the mechanism of the hypoglycaemic action of biguanides have raised considerable controversy in recent years. The possibility that these drugs may act through inhibition of oxidative phosphorylation, which may increase the glucose uptake of peripheral tissues<sup>1</sup>, has been frequently emphasized<sup>2-5</sup>, but experiments on the kinetics of glucose loads<sup>6</sup> as well as the demonstration that no correlation exists between the hypoglycaemic effect of various biguanides and their inhibitory action on oxidative phosphorylations<sup>7,8</sup> did not support this hypothesis. Moreover, it is now well established that the biguanide drugs have no effect on the glycaemia of normal animals and men, and that their action is restricted to the diabetic and fasting animal. Thus it appeared reasonable to assume that they may interfere with one or more metabolic pathways which are widely different in the normal and diabetic organism. One of these is the gluconeogenic pathway, resulting in the synthesis of glucose from metabolites containing three or four carbon atoms, including amino-acids. The possibility that such a mechanism may explain the anti-diabetic action of at least two biguanides (phenylethylbiguanide (PEBG) and dimethylbiguanide (DMBG)) has been investigated.

In the first series of experiments gluconeogenesis was induced in normal rats (200 g) and guinea-pigs (300 g), after a fasting period of 24 h by injection of hydrocortisone hemisuccinate (2 mg/100 g) and estimated 3 h after the injection by measuring the glycogen content of the liver<sup>9</sup>, the blood glucose level<sup>10</sup> and the incorporation of carbon-14-pyruvate into blood glucose. The latter compound was isolated by paper chromatography. Table 1 shows the results of these experiments, either on animals treated with hydrocortisone only, or on animals pre-treated with a biguanide compound 1 h before the hydrocortisone injection. It may be seen that the biguanides strongly inhibit the effects induced by cortisone on the metabolism parameters already mentioned.

In a second series of experiments (Table 2) the specific inhibition by biguanides of gluconeogenesis from various substrates has been determined by the same methods; an additional assay of the level of amino-acids in blood plasma was performed using the ninhydrin method<sup>11</sup>.

Table 1. INFLUENCE OF BIGUANIDES ON THE CORTISONE INDUCED GLUCONEOGENESIS IN THE STARVED RAT AND GUINEA-PIG

Treatment	Glycogen (mg/g)	Blood (g/l.)	Glucose from <sup>14</sup> C pyruvate specific activity c.p.m./mg glucose
(1) Rat			
0	0.075 ± 0.012	0.62 ± 0.08	1,070 ± 102
Cortisone (3 mg)	7.250 ± 0.12	1.19 ± 0.15	2,860 ± 107

" " " " " " " "	PEBG (10 mg)	6.40	0.20	10.2	

\* Estimated against a standard of pure L-alanine.

Control determinations by paper chromatography showed that an increase in ninhydrin positive material reflected the actual amino-acid content of the plasma and not an increase in urea. Both biguanides strongly inhibit gluconeogenesis from pyruvate and alanine whereas only limited effects are obtained when the substrate is aspartic acid. In addition PEBG strongly increases the level of amino-acids in the blood, a result which suggests that its mechanism of action may not be completely identical with the mechanism of action of DMBG.

In an attempt to confirm these results on the gluconeogenesis of an isolated tissue, a third series of experiments has been performed with incubated rat kidney slices by measuring the neoformation of glucose, according to the method developed by Krebs *et al.*<sup>12</sup>. Table 3 shows the results of these experiments in the presence of various substrates: it appears that DMBG preferentially inhibits the conversion of pyruvate and lactate to glucose, with a somewhat less marked effect on alanine and almost no effect on glutamate and oxaloacetate; conversely, PEBG seems to inhibit specifically gluconeogenesis from amino-acids like alanine and glutamic acid and from oxaloacetate. Hence it appears that the inhibitory action of biguanides on gluconeogenesis is perfectly reproducible on an isolated tissue and seems to exhibit a pronounced substrate specificity, according to the inhibitor used.

Two conclusions may be drawn from these experiments. First, it appears that the marked inhibition of gluconeogenesis by all the substrates used, except aspartate, under the influence of biguanides offers a reasonable explanation of the hypoglycaemic action of these drugs, especially since their concentrations throughout this work are near the concentrations which have been used in the diabetic organism<sup>13</sup>. Thus it may be assumed that the inhibition of cortisone-induced gluconeogenesis which has been observed reflects an interference of the drugs with the conversion of endogenous substrates to

Table 3. INFLUENCE OF PHENYLETHYLBIGUANIDE (PEBG) AND DIMETHYLBIGUANIDE (DMBG) ON THE GLUCONEOGENESIS OF ISOLATED RAT KIDNEY SLICES

Substrates (molar conc.)	Biguanide (molar conc.)	Glucose synthesized (mg/g slices fresh weight/30 min)	Inhibition (per cent)
(1) 0	0	0.25 ± 0.1	0

" " " " " " " "	PEBG (2.10 <sup>-3</sup> M)	1.00 ± 0.26	53
(5) Sodium oxaloacetate (10 <sup>-3</sup> M)	0	3.10 ± 0.18	0
" " " " " " " "	DMBG (10 <sup>-4</sup> M)	3.05 ± 0.315	1.6
" " " " " " " "	PEBG (5.10 <sup>-5</sup> M)	1.56 ± 0.20	49.6

glucose and not an inhibition of the *de novo* synthesis of specific enzymes involved in the gluconeogenesis of liver and kidney<sup>14</sup>. It may be added that the possibility that PEBG interferes with gluconeogenesis had been mentioned by Williams *et al.*<sup>15</sup> after experiments performed with alanine on guinea-pigs.

Second, concerning the specific action of either biguanide on gluconeogenesis from different substrates, it may be premature to conclude from these experiments that these actions are due to the inhibition of specific enzymes, because gluconeogenesis involves a complex regulatory mechanism of carboxylation by pyruvate carboxylase<sup>16</sup> of transamination steps<sup>17</sup> and of an exchange of substrates between mitochondria and cytoplasm<sup>18</sup>. It seems, however, from these results that both biguanides used may provide useful laboratory tools for the study of gluconeogenic pathways at the cellular level.

### $\beta$ -Xylosidase and $\beta$ -Galactosidase Activities of Mammalian Connective Tissues and Other Sources

It has been shown that the sequence: -glucuronate-galactose-galactose-xylose-serine- serves as a chemical "bridge" between the polysaccharide and polypeptide components in a number of sulphated mucosubstances including heparin and chondromucoprotein<sup>1-6</sup>. A chondropeptide fraction isolated from bovine tracheal cartilage<sup>6</sup> seems to be hydrolysed by a  $\beta$ -xylosidase present in almond emulsin at the point of the carbohydrate-peptide linkage<sup>7</sup>. This communication describes the  $\beta$ -galactosidase and  $\beta$ -xylosidase activities of cartilage, other mammalian tissues, and also in jack beans.

When slices of bovine nasal and rabbit ear cartilage are incubated at 37° C with *o*- or *p*-nitrophenyl- $\beta$ -D-xylopyranoside<sup>7,8</sup> or with *o*- or *p*-nitrophenyl- $\beta$ -D-galactopyranoside

in sodium citrate buffers (0.15 moles/l., pH 4.8) in the presence of 1 mmolar sodium azide (as a bacteriostat), the nitrophenols are slowly liberated. Both enzyme activities are greater in young cartilage (for example, from 6 week old rabbits or 1 year old bullocks) than in cartilage of fully developed and aged animals (2 year old rabbits, 4 year old cattle). These cartilage glycosidases are distinguishable from other endogenous chondrolytic enzyme(s), which behave as proteases and release chondropeptides into the incubation medium<sup>9,10</sup>. The properties of the glycosidases differ from those of the proteases in (i) the lesser enzyme activity at 55° C than at 37° C; (ii) the relative insensitivity to 20 mmolar chloroquine; (iii) the different sensitivity to mercurial inhibitors (see Table 1). Table 1 also shows that the xylosidase and galactosidase activities in a purified fraction<sup>7</sup> of almond emulsin can be distinguished from the corresponding animal enzymes by their relative insensitivity to mercuric ions. Thiol-neutralizing agents (*N*-ethylmaleimide and iodoacetate, 1 mmolar) did not inhibit the mercury-sensitive cartilage glycosidases.

The cartilage and emulsin xylosidases failed to hydrolyse either *o*-nitrophenyl-2,3,4-tri-*O*-acetyl- $\beta$ -D-xylopyranoside or *p*-nitrophenyl- $\alpha$ -D-xylopyranoside (synthesized and kindly donated by Mr. M. Higham), which indicates specificity for unsubstituted  $\beta$ -xylosides.

Both glycosidases were extracted simultaneously by 0.15 molar sodium chloride from powdered frozen rabbit ear cartilage and remained in the particles and supernatant after centrifugation at 80,000 *g* for 30 min. 'Triton X-100', which at a concentration of 0.1 per cent v/v increases the activity of many lysosomal enzymes, did not affect the glycosidase activities of these uncentrifuged extracts.

The cartilage slices incubated at pH 4.8 at 37° C generally liberated two or three times the quantity of *o*- and *p*-nitrophenol from the galactoside substrates compared with the corresponding xyloside substrates.  $\beta$ -Galactosidase activity also occurred in other tissues where  $\beta$ -xylosidase was found, for example rabbit aorta, beef cornea (approximately equal enzyme activities in the epithelial and stromal fractions), bovine cuspidal and semilunar heart valves, tissue cultures of murine mast cells (kindly donated by Mr. J. F. Wheldrake), mouse skin and many rat tissues (lung, spleen, brain, kidney, heart and liver). Rat serum, on the other hand, contained no detectable  $\beta$ -xylosidase although  $\beta$ -galactosidase was present. Horse serum (used for culturing mast cells) contained neither enzyme.

$\beta$ -Xylosidase and  $\beta$ -galactosidase were also present in particulate fractions prepared by sedimenting (between 3,000 and 20,000 *g* for 20 min) homogenates of beef heart, rat brain, lung, kidney, liver and spleen. The last three tissues also exhibited  $\beta$ -glucosidase activity.

Aqueous extracts of jack bean meal contained  $\beta$ -xylosidase and  $\beta$ -glucosidase of similar activity and a  $\beta$ -galactosidase of greater activity. Other glycosidases have been recently reported to be present in jack bean meal<sup>11</sup>. The  $\beta$ -xylosidase from this source was readily distinguished from the accompanying  $\beta$ -galactosidase because it was not sensitive to mercuric ions at a concentration which abolished the  $\beta$ -galactosidase activity.

With all the animal glycosidases (regardless of tissue source), the galactosidase activity was inhibited by 25

Table 1. COMPARISON OF  $\beta$ -XYLOSIDASE (Xyl),  $\beta$ -GALACTOSIDASE (Gal) AND  $\beta$ -GLUCOSIDASE (Glu), AND CHONDROMUCOPROTEASE (F) ACTIVITIES

pH optimum	Rat liver			Rabbit ear cartilage			Bovine nasal cartilage			Almond emulsin			Jack bean meal		
	Xyl 5.0	Gal 3.4 and 3.8	Glu 5.2- 5.4	Xyl 4.8	Gal 4.8	P 4.8	Xyl 4.4- 4.6	Gal 3.6- 4.2	P 4.6- 5.0	Xyl 4.8	Gal 4.8	Glu 5.4	Xyl 4.0- 4.4	Gal 4.2- 4.6	Glu 5.6- 6.0
Ratio activities at 55°/37° C	—	—	—	<0.2	<0.2	>1.0	0.3	—	1.8	—	—	—	—	—	—
Percentage inhibitions by 20 mmolar chloroquine phosphate	—	—	—	18	10	48	24	18	60	—	—	—	—	—	—
0.5 mmolar mercuric chloride	100	100	100	100	100	10	100	100	0	0	0	0	0	100	0
25 mmolar D-galactono-1,4-lactone	0	100	—	0	85	0	—	—	—	70	80	80	0	100	0
25 mmolar D-glucono-1,4-lactone	100	0	—	90	0	15	—	—	—	100	100	100	20	0	85

Chondromucoprotease activity was measured turbidometrically with rivanol<sup>12,13</sup>. *o*-Nitrophenyl glycosides (2.5 mmoles/l.) were incubated in 0.15 molar citrate buffer (pH 4.8) at 37° C with cartilage slices or homogenates. *o*-Nitrophenyl glycosides (1.5 mmoles/l.) were used with purified almond emulsin extracts<sup>7</sup> at 30° C. The liberated nitrophenol was measured by its light absorption at 416 m $\mu$  after addition of sodium carbonate (0.25 moles/l.). The colour was extracted from turbid solutions into *n*-butanol.

mmolar D-galactono-1,4-lactone and not by 25 mmolar D-glucono-1,4-lactone. Conversely xylosidase activity was inhibited by the gluconolactone and not by the galactono-lactone<sup>12</sup>. The xylosidase and glucosidase activities of rat liver particles (lysosomes) and nasal and ear cartilage could be distinguished by their different pH optima.

The apparent ubiquity of these glycosidases in connective tissues may be of considerable relevance to the turnover of some polysaccharide-protein complexes.

### **In vitro Anticholinesterase Activity of Certain N-Methylcarbamate Insecticides compared with their N-Acyl Derivatives**

THE insecticidal activity of certain N-acyl N-methylcarbamate insecticides has been reported recently by Fraser *et al.*<sup>1</sup>. Reay and Lewis<sup>2</sup> showed that the N-acetyl derivative of 1-naphthyl N-methylcarbamate (carbaryl) was nearly 100 times less inhibitory towards honeybee head cholinesterase (ChE) *in vitro* than the parent compound (see also Table 1). It is the purpose of this communication to report that the N-acylation of several other N-methylcarbamates leads to a marked reduction in *in vitro* anticholinesterase activity against honeybee head ChE.

The method used for the assay of ChE has already been described in full<sup>3</sup>. The insecticides used were of the general structure I or II, where R' is an aromatic nucleus and R'' is a simple alkyl group.

They were dissolved in 'AnalaR' acetone for addition to the assay mixture, and the activity of ChE in the presence of insecticide was compared with that in the presence of acetone only. The results are summarized in Table 1.

It is clear that N-acylation of all the N-methylcarbamates tested causes a marked drop in their activity against honeybee head ChE *in vitro*. The fall in activity is, in fact, less in the case of carbaryl, already cited<sup>2</sup>, than for any of the others; the factor involved is nearly a thousand in most instances. It is also apparent, however, that acylation with side chains of increasing length, up to C=6, increases the activity against ChE compared with that of the acetyl derivative, though the activity of the parent carbamate is on no occasion fully restored. N-acylation with a dodecanoyl group, however, gives decreased activity against ChE.

Because the lengthening of the nitrogen-attached side-chain from C=2 to C=6 leads to an increase in inhibition

Table 1. *In vitro* ANTICHOLINESTERASE ACTIVITY OF CARBAMATES

Insecticide	IC 50*
1-Naphthyl N-methylcarbamate (carbaryl)	4.75 × 10 <sup>-4</sup>
1-Naphthyl N-acetyl-N-methylcarbamate	4.0 × 10 <sup>-4</sup>
1-Naphthyl N-propionyl-N-methylcarbamate	8.5 × 10 <sup>-7</sup>
1-Naphthyl N-butyryl-N-methylcarbamate	6.0 × 10 <sup>-7</sup>
2-Isopropylphenyl N-methylcarbamate	4.25 × 10 <sup>-7</sup>
2-Isopropylphenyl N-acetyl-N-methylcarbamate	1.4 × 10 <sup>-4</sup>
2-Isopropylphenyl N-hexanoyl-N-methylcarbamate	8.0 × 10 <sup>-6</sup>
2-Isopropylphenyl N-dodecanoyl-N-methylcarbamate	2.2 × 10 <sup>-4</sup>
3-Isopropylphenyl N-methylcarbamate	2.2 × 10 <sup>-4</sup>
3-Isopropylphenyl N-acetyl-N-methylcarbamate	2.0 × 10 <sup>-4</sup>
3-Isopropylphenyl N-butyryl-N-methylcarbamate	8.4 × 10 <sup>-4</sup>
3-Isopropylphenyl N-hexanoyl-N-methylcarbamate	2.3 × 10 <sup>-4</sup>
2-Isopropoxyphenyl N-methylcarbamate	7.5 × 10 <sup>-7</sup>
2-Isopropoxyphenyl N-acetyl-N-methylcarbamate	6.5 × 10 <sup>-4</sup>
2-Isopropoxyphenyl N-butyryl-N-methylcarbamate	3.0 × 10 <sup>-4</sup>
4-Dimethylamino-3,5-xylyl N-methylcarbamate	1.25 × 10 <sup>-4</sup>
4-Dimethylamino-3,5-xylyl N-acetyl-N-methylcarbamate	4.0 × 10 <sup>-4</sup>

\* IC 50 = Concentration (moles/l.) for 50 per cent ChE inhibition.

of ChE, it is clearly not possible to postulate that it is steric hindrance which is responsible for the decrease in ChE inhibition on N-acetylation. Steric hindrance could, however, be an important reason for the loss of activity of the dodecanoyl derivative. It seems more likely that the decrease of activity on acetylation results from the change of electron distribution brought about by the introduction of the electron-withdrawing acetyl —C=O group. This hypothesis is analogous to those proposed by Kolbezen *et al.*<sup>3</sup> and Metcalf *et al.*<sup>4</sup> to explain the activities of certain other substituted carbamates. The withdrawal of electrons from the —O.CO.N— group of the carbamate will result in the formation of a weaker bond between the inhibitor and ChE, because it is this group that has been found to be the point of attachment to the enzyme<sup>5-7</sup>. The increased activity of the longer-chain N-acylated compounds, however, cannot be explained along these lines, because the alkyl group has little electron-shifting capacity and would, if anything, tend to increase the electron-withdrawing capacity of the acyl group (compare Kolbezen *et al.*<sup>3</sup>). This means that some factor other than electron density and steric hindrance must be important in determining the affinity of a carbamate inhibitor for ChE.

I thank Dr. J. Fraser for synthesis of the acyl carbamate insecticides, and many other colleagues for helpful discussion of the results.

### **Activation of Honeybee Head Cholinesterase by Water-miscible Organic Solvents**

COLHOUN<sup>1</sup> showed that many water-miscible organic solvents increased the activity of cholinesterase (ChE) preparations from the cockroach *Periplaneta americana*. Shatoury<sup>2,3</sup> showed that a similar activation occurred in the case of the housefly *Musca domestica*, though here n-butanol only was used as "activator", and the effect was far less marked. It has now been found that an even larger activation than that recorded by Colhoun can be achieved by addition of certain water-miscible organic

solvents, notably *n*-butanol and *n*-pentanol, to ChE preparations from heads of the honeybee *Apis mellifera*.

The method of assay has been described fully elsewhere<sup>4</sup>. A number of organic solvents have been investigated and a range of solvent concentrations tested in the case of acetone, the solvent most frequently used for *in vitro* investigations of ChE inhibition by insecticides (see, for example, refs. 5 and 6). These results are summarized in Table 1 and Fig. 1.

Table 1. EFFECT OF ADDITION OF VARIOUS SOLVENTS\* TO HONEYBEE ChE ASSAYS

Organic solvent	ChE activity†	Activation (per cent control)
None (control)	30.1	—
Acetone	48.2	158
Methanol	36.0	120
Ethanol	44.2	147
<i>n</i> -Propanol	68.5	228
Isopropanol	63.5	211
<i>n</i> -Butanol	124.0	412
Isobutanol	61.0	202
<i>s</i> -Butanol	93.5	310
<i>t</i> -Butanol	57.2	190
<i>n</i> -Pentanol	136.8	454
<i>n</i> -Hexanol	36.8	122
2-Methoxy-ethanol	49.4	164

\* 0.3 ml. added to assay, 15 ml. total.

† ChE activity measured in  $\mu$ l. 0.01 normal sodium hydroxide/min. at pH 6.95 and 30° C (ref. 4).

It is clear that a number of organic solvents can "activate" honeybee-head ChE preparations, but that maximum activation occurs with *n*-butanol and *n*-pentanol. Branched chain alcohols are less effective and higher alcohols are immiscible with the assay mixture. The amount of acetone added markedly alters the degree of activation up to about 5 per cent of the total volume; thereafter, increasing the concentration has less effect (Fig. 1). The increase in enzyme activity has been shown to be virtually instantaneous (Fig. 2).

Increases in activity up to 120 per cent of the control have also been brought about by the addition of surface-active agents, for example, sodium deoxycholate (compare Shatoury<sup>3</sup>, Ord and Thompson<sup>7</sup>); the addition of organic solvents to an assay mixture treated with deoxycholate resulted in additional activation. Preparations of ChE which have been extracted with diethyl ether showed increased activity when compared with unextracted preparations; this activation, however, may result solely from ether in solution in the aqueous phase.

Fig. 1. Activity of bee-head ChE in the presence of increasing concentrations of acetone.

Fig. 2. Activity of a bee-head ChE preparation alone and after addition of acetone (shown thus ↓).

Various reasons for these increases in activity of ChE have been given by other workers<sup>1-3</sup>, but there seems to be no overwhelming evidence in favour of any one theory. One factor which might be important is the lipid-solubility of the "activator". It is possible that ChE exists *in vivo* in a lipoprotein complex, which is severely disrupted by the extraction process, and that this results in loss of activity due to blockage of the active sites of the enzyme with lipid material. The effect of organic solvents and surface-active agents might therefore be explained by solubilization of this interfering material. This theory is not inconsistent with the observation of Metcalf and March<sup>6</sup> that bee-head ChE increases in activity on storage.

### Relationship between Parathyroid Function and Serum Aminopeptidase A Activity

AMINOPEPTIDASE A, a mammalian peptidase specific for the hydrolysis of N-terminal  $\alpha$ -L-glutamyl and aspartyl residues, has been found in many tissues such as the epithelium of guinea-pig pancreatic duct, islets of Langerhans and human and rat glomeruli<sup>1,2</sup>. It has been found in rat serum as well as in human serum<sup>3,4</sup>, and this serum enzyme activity is markedly activated specifically by calcium.

During investigations of the effects of the parathyroid function on some serum enzyme activities, the activities of aminopeptidase A and alkaline phosphatase in serum were found to have a significant positive correlation with

the parathyroid functional states. On the other hand, similar serum peptidase, leucine aminopeptidase, on which calcium has no effect, showed no correlation with the parathyroid functional states.

Various functional states of the parathyroid glands of rats can be observed histologically during pregnancy, lactation and ablation, and so rats in these states were used as experimental animals, and they were killed at different times. Rats of various ages from the fetus (19 days old) to adult (16 months old) were also used as experimental animals. Adult female or male rats were used as normal controls, and sex differences were not observed. Rats of the Wistar strain were used throughout the experiments. Blood samples were collected by means of heart puncture or decapitation, and serum calcium, inorganic phosphorus and alkaline phosphatase were measured as indicators of the functional state of the parathyroid glands. The functional states of the parathyroid glands were examined histologically, and the morphological changes were compared with calcium, inorganic phosphorus, and alkaline phosphatase activity in the serum. The alkaline phosphatase activity of serum in rats increased markedly during lactation, and this increase could be, in a part, independent of hyperfunction of the parathyroid glands. These values were therefore omitted, and will be reported elsewhere.

About eighty sera of rats with parathyroid glands in various functional states were tested to determine the concentrations of calcium and inorganic phosphorus, and the activity of alkaline phosphatase and aminopeptidase A, with  $\alpha$ -L-glutamyl- $\beta$ -naphthylamide as substrate, and for the activity of leucine aminopeptidase L-leucinamide or L-leucyl- $\beta$ -naphthylamide as substrate.

Microassays using 0.1 ml. of serum were carried out by a modification of the usual methods for calcium<sup>5</sup>, inorganic phosphorus<sup>6</sup>, and alkaline phosphatase<sup>7</sup>. A microassay of  $\alpha$ -L-glutamyl- $\beta$ -naphthylamide or L-leucyl- $\beta$ -naphthylamide-splitting enzyme activity was established by a method based on that of Glenner<sup>2</sup>. The activity of the L-leucinamide-splitting enzyme was measured by a new method based on the isolation by paper chromatography and colorimetric assay of L-leucine liberated from the substrate. Enzyme assay was carried out at 37° C.

The ranges for experimental values and the normal control values with standard deviations (in parentheses) were as follows: calcium, 22–233 (145  $\pm$  39) mg/l. of serum; inorganic phosphorus, 57–228 (118  $\pm$  38) mg/l. of serum; alkaline phosphatase, 23–208 (127  $\pm$  23)  $\mu$ moles of inorganic phosphorus/min./l. of serum;  $\alpha$ -L-glutamyl- $\beta$ -naphthylamide-splitting enzyme, that is, aminopeptidase A, 2.0–29.4 (13.1  $\pm$  6.2)  $\mu$ moles of  $\beta$ -naphthylamine liberated from  $\alpha$ -L-glutamyl- $\beta$ -naphthylamide/min./l. of serum; L-leucyl- $\beta$ -naphthylamide-splitting enzyme, 6.2–42.3 (29.9  $\pm$  8.4)  $\mu$ moles of  $\beta$ -naphthylamine liberated from L-leucyl- $\beta$ -naphthylamide/min./l. of serum; L-leucinamide-splitting enzyme, that is, leucine aminopeptidase, 1.2–76.5 (44.2  $\pm$  8.5)  $\mu$ moles of L-leucine liberated from L-leucinamide/min./l. of serum.

Correlation coefficients (*r*) are shown in Table 1. There is a positive correlation between  $\alpha$ -L-glutamyl- $\beta$ -naphthylamide-splitting enzyme and calcium or alkaline phosphatase activity, as well as between calcium and alkaline

phosphatase activity. There is a negative correlation between inorganic phosphorus and  $\alpha$ -L-glutamyl- $\beta$ -naphthylamide-splitting enzyme or calcium. There is, however, almost no correlation between L-leucyl- $\beta$ -naphthylamide-splitting enzyme or L-leucinamide-splitting enzyme and calcium, inorganic phosphorus, or alkaline phosphatase activity.

The activity of aminopeptidase A was measured in a saturated amount of calcium to obtain the maximum velocity, and so the enzyme activity measured is not influenced by the differences in calcium concentrations in serum samples. It is concluded, therefore that the parathyroid function might exert an influence on the concentration of aminopeptidase A protein in serum. The origin of aminopeptidase A in serum is not yet clear, but it is interesting that the enzyme which needs calcium as co-factor can be regulated by parathyroid function.

### Separation of a Hydrolase from a Pectic Acid Transeliminase in Cell Extracts of a *Bacillus*

In the past few years it has become increasingly evident that the principal mechanism involved in bacterial breakdown of pectic substances is a transelimination reaction resulting in the formation of unsaturated uronides<sup>1–5</sup>. So far as we know, no one has isolated a true hydrolase from bacteria. The presence of a hydrolase, however, can be deduced from the results obtained by Preiss and Ashwell<sup>3</sup>. Based mainly on the products found, they concluded that the cell extracts of a pseudomonad must have contained both transeliminase and hydrolase activities. These investigators did not isolate the hydrolase.

An attempt was made in this laboratory to isolate a bacterial hydrolase. In preliminary investigations, twenty cultures of bacteria which decompose pectic acid were isolated on a sodium polypectate medium<sup>3</sup> from various soils and manures for a survey of the production of a bacterial hydrolase. The results of this survey indicated that the cell extracts of one strain of an aerobic species of *Bacillus* possessed, in addition to a transeliminase, considerable hydrolase activity. The hydrolase has been separated from the transeliminase by ammonium sulphate fractionation followed by chromatography on a DEAE cellulose column. When the supernatant solution of the cell extract was fractionated with solid ammonium sulphate, all the hydrolase activity was precipitated in the fraction of 0–0.5 saturation, but only 30 per cent of the transeliminase activity was present in this precipitate. The fraction obtained from 0–0.4 saturation was further fractionated on a DEAE cellulose column. After the preparation had been dialysed against water, it was applied to a column of DEAE cellulose, 1.5 cm  $\times$  20 cm, which had been previously equilibrated with 0.05 molar *tris* buffer, pH 7.5. The column was eluted by a stepwise method with a solvent system consisting of 0.1 molar *tris* buffer, pH 7.5, 0.02 per cent cysteine hydrochloride, and increasing concentrations of sodium chloride. The following elution pattern was used: 75 ml. of buffer solution, 50 ml. each of buffer plus 0.1 molar salt, buffer plus 0.2 molar salt, and buffer plus 0.3 molar salt. The trans-

Table 1. VALUES OF CORRELATION COEFFICIENT

Correlation between	<i>r</i>	No. of cases
$\alpha$ -L-Glutamyl- $\beta$ -naphthylamide-splitting enzyme/calcium	0.57	63
$\alpha$ -L-Glutamyl- $\beta$ -naphthylamide-splitting enzyme/inorganic phosphorus	-0.54	65
$\alpha$ -L-Glutamyl- $\beta$ -naphthylamide-splitting enzyme/alkaline phosphatase	0.41	44
L-Leucyl- $\beta$ -naphthylamide-splitting enzyme/calcium	0.20	67
L-Leucyl- $\beta$ -naphthylamide-splitting enzyme/inorganic phosphorus	-0.25	68
L-Leucyl- $\beta$ -naphthylamide-splitting enzyme/alkaline phosphatase	0.10	46
L-Leucinamide-splitting enzyme/calcium	0.12	57
L-Leucinamide-splitting enzyme/inorganic phosphorus	-0.05	54
L-Leucinamide-splitting enzyme/alkaline phosphatase	0.13	38
Calcium/inorganic phosphorus	-0.38	60
Calcium/alkaline phosphatase	0.43	42

eliminase was eluted by the buffer while the hydrolase was eluted by the 0.2 molar salt plus buffer solution. The transeliminase activity was measured by a pectic acid plate method<sup>6</sup> or by measurement of the increase in absorbancy at 232 m $\mu$ , while hydrolase activity was determined quantitatively by measurement of decrease in absorbancy at 232 m $\mu$  with the unsaturated substrates and qualitatively by paper chromatography for both unsaturated and saturated substrates.

The hydrolase of the *Bacillus* species seemed to be quite different from plant and fungal polygalacturonases<sup>7,8</sup> in that the rate of hydrolysis of unsaturated uronides was inversely proportional to chain length. The enzyme attacks from the non-reducing end liberating either unsaturated or saturated monomers depending on the substrate used. In preliminary investigations, it was found also that the enzyme did not require calcium ions for its activity and that its optimum pH seemed to be considerably lower than that of the transeliminase.

Exocellular pectolytic enzymes of the bacterium showed only transeliminase activity. The transeliminase has characteristics similar to that of other bacterial transeliminases in that it has a high optimum pH and requires calcium ions for activity. Paper chromatographic analyses showed that the enzyme attacked higher uronides in a random manner but it did not seem to attack trigalacturonic acid under the same conditions.

### Activity of Malic Dehydrogenase of the Symbionts and Fat Bodies of a Cockroach

MALIC dehydrogenase is an enzyme of the tricarboxylic acid cycle which catalyses the oxidation of malate to oxalacetate in the presence of NAD<sup>+</sup>. It has been found in the fat bodies of the cockroaches, *Blattella germanica* and *Periplaneta americana*<sup>1-3</sup>, as well as in similar tissues of the locust, *Locusta migratoria*<sup>4</sup>. The purpose of our investigation was, therefore, to determine whether the activity of this enzyme in the fat bodies of the cockroach, *Leucophaea maderae*, is caused solely by the action of these tissues, the symbionts, or both.

Cockroaches were reared according to the method of Pierre<sup>5</sup>, and the symbionts were isolated from the fat bodies according to the methods of Begg and Sang<sup>6</sup>, Pant, Nayar and Gupta<sup>7</sup> and Pierre<sup>5</sup>. Investigation of the activity of the enzyme was carried out on homogenates made from 1-g weights of materials of the symbionts (48-h-old cultures grown on *Neurospora* agar for luxuriant growth), similar weights of the fat bodies of normal adults and nymphs (sixth to eighth instars), and fat bodies of corresponding aposymbiotic insects (devoid of symbionts). The materials were homogenized with a sterile tissue grinder in 2 ml. of 0.03 molar phosphate buffer at pH 7.4. Sufficient of the same buffer and 2 ml. of 0.2 per cent NAD<sup>+</sup> were added to make a concentration of 3.3 per cent, and the homogenates were incubated at 30° C in a constant temperature bath for 0.5 h to oxidize the endogenous substrates. At the end of incubation, they were assayed for the activity of the enzyme.

Determination of the activity of malic dehydrogenase was performed according to the method of Thunberg<sup>8</sup>. The details of this method are as follows: 0.25 ml. of 0.25 molar sodium malate (substrate), 0.5 ml. of methylene blue (1 : 10,000), and 2.35 ml. of 0.03 molar phosphate buffer, pH 7.4, were placed in the main portion of the tube; 0.1 ml. of the homogenate was placed in the side arm. Two standards were prepared; one contained all the ingredients of the reaction tube except the substrate, and 2.6 ml. of buffer instead; and the other was a similar standard the homogenate of which was inactivated by boiling, and which contained 0.1 ml. of methylene blue, and 2.75 ml. of the buffer instead. All the tubes were sealed and evacuated for 5 min. They were then immersed in a constant temperature water bath at 30° C, and the time for 90 per cent of the indicator to be decolorized was determined visually. Accordingly, the activity of the enzyme was expressed as the reciprocal of the time in min required for 90 per cent decoloration of the indicator.

Spectrophotometric determination of malic dehydrogenase was performed with homogenates identical to those already outlined by the Thunberg technique. Assays of the enzyme activity were made with a spectrophotometer, at a wavelength of 340 m $\mu$ , according to the methods of Faulkner<sup>9</sup> and Protá<sup>10</sup>. The cuvettes used contained 0.1 ml. of homogenate, 0.25 ml. of 0.25 molar sodium malate, 0.25 ml. of 0.2 per cent NAD<sup>+</sup>, 0.25 ml. of 1.0 per cent KCN (oxalacetate inhibitor), and 2.15 ml. of 0.03 molar phosphate buffer, pH 7.4. The instrument was set at zero optical density with 3 ml. of all the ingredients of the cuvette except the NAD<sup>+</sup>. Recordings were made at zero time, and then at 5 min intervals for 20 min. The enzyme activity was then expressed as the change in optical density which occurred between zero time and the end of the experiment. Twenty determinations of the activity of the enzyme were performed by each method. This necessitated the use of individual insects, and fresh cultures of the symbionts at each trial.

The results obtained for the activity of malic dehydrogenase investigated by the Thunberg technique<sup>8</sup> in the materials of the symbionts, and those of the normal adults and nymphs, were 0.017, 0.018, and 0.043 respectively. Corresponding activities obtained in the aposymbiotic insects were 0.002 and 0.003 respectively. These activities are expressed as the reciprocal of the time in min required for 90 per cent decoloration of methylene blue. Spectrophotometric results of the activities obtained for materials of the symbionts, and those of the normal adults and nymphs were 0.116, 0.146, and 0.222 respectively; and corresponding results for materials of the aposymbiotic insects were 0.025 and 0.029 respectively. These activities are expressed as the change in optical density of the reaction mixture between readings at zero time and after 20 min. A representation of the spectrophotometric measurements of the activities in materials of the symbionts and normal insects is shown in Fig. 1. These graphs portray the rising change in the optical density of malate as the latter is converted to oxalacetate in the presence of the enzyme.

The results of this investigation have revealed that (a) the highest concentration of malic dehydrogenase is contained in the normal nymphal fat bodies; (b) a higher concentration of the enzyme is found in normal fat bodies than in the materials of the symbionts; (c) despite the high concentration of the enzyme in nymphal tissue, this concentration decreases as adulthood is attained; (d) a very low concentration of the enzyme exists in aposymbiotic fat bodies; and (e) the symbionts contribute almost all of the enzyme found in normal fat bodies.

Dubowsky and Pierre<sup>11</sup> have demonstrated in this laboratory that the malic enzyme of the fat bodies of this cockroach, *L. maderae*, is confined to the action of these tissues. It seems that, when this malic enzyme of the fat bodies reversibly converts malate to pyruvate, the

Fig. 1. Graphs showing the activities of malic dehydrogenase from the materials of (a) nymphs; (b) normal adults; and (c) symbionts in the presence of malate.

malic dehydrogenase of the symbionts in turn converts the malate so reformed to oxalacetate.

### Activity of Isocitric Dehydrogenase in the Fat Bodies of the Cockroach, *Leucophaea maderae* (F)

ISOCITRIC dehydrogenase, an enzyme of the tricarboxylic acid cycle, is responsible for the formation of  $\alpha$ -keto-glutarate from isocitrate. During the reaction, oxalosuccinate is formed (as an intermediate) owing to the presence of two pyridine nucleotide-linked dehydrogenases in biological systems. One dehydrogenase is linked with NAD and the other is linked with NADP. They first catalyse the oxidation of isocitrate, and then its decarboxylation in the presence of the manganous ion. If NADP is used in the reaction, it is reduced and, because of the reversibility of the process, carbon dioxide is fixed in oxalosuccinate and isocitrate. Isocitric dehydrogenase has been isolated from heart tissue of the pig<sup>1</sup>, yeasts<sup>2</sup>, and various animal tissues<sup>3</sup>. This enzyme was discovered in the supernatant fraction of the homogenates of the fat bodies of the cockroach, *Periplaneta americana*<sup>4,5</sup>. Its presence has been reported in the haemolymph of the mealworm, *Tenebrio molitor*, by Protta (see previous communication). Hence, the purpose of this investigation was twofold: to determine whether this enzyme could be detected in normal and aposymbiotic fat bodies of the cockroach, *Leucophaea maderae*; and to determine whether the presence of the

enzyme in this tissue is due to the action of the tissue, the symbionts or both.

Cockroaches were reared, with slight modification<sup>6</sup>, by the methods described in the preceding communication, and homogenates were prepared and enzymes were assayed also in the way described in the previous communication.

Spectrophotometric determination of the activity of isocitric dehydrogenase was performed according to the method of Protta (see preceding communication) with a spectrophotometer at a wavelength of 340 m $\mu$ . The instrument was blanked with 3 ml. of 0.03 molar phosphate buffer at pH 7.4. The cuvettes used contained 0.5 ml. of  $6 \times 10^{-3}$  molar manganous chloride; 1 ml. of 0.2 per cent sodium isocitrate (substrate); 0.1 ml. of homogenate; 0.5 ml. of 1 per cent NADP<sup>+</sup>; and 0.9 ml. of 0.03 molar phosphate buffer, pH 7.4. The optical density of reaction mixtures was measured at zero time, and then at 1 min intervals until the end of the experiment. The enzyme activity was then determined by the change in optical density of the reaction mixture which occurred between the readings at zero time and at the end of the experiment.

Assays of enzyme activity were also performed according to the methods of Thunberg (see preceding article), with materials identical to those used for the first method. One millilitre of homogenate was placed in the side arm of the tube; and 0.5 ml. of methylene blue (1:10,000); 1 ml. of 1 per cent NADP<sup>+</sup>; 1 ml. of 0.2 per cent sodium isocitrate; 0.5 ml. of  $6 \times 10^{-3}$  molar manganous chloride; and 0.5 ml. of 0.03 molar phosphate buffer, pH 7.4, were placed in the main part of the tube. The two standards were: one which contained all the ingredients of the reaction tube except the substrate, which had 1.5 ml. of the buffer instead; and a similar standard which contained 0.05 ml. of the methylene blue instead of 0.5 ml., 0.95 ml. of buffer, and in which the enzyme had been inactivated by boiling. All tubes were sealed and evacuated for 5 min. They were then immersed in a constant temperature water bath at 30° C, and the time in min required for 90 per cent of the indicator to be decolorized was determined visually. The enzyme activity was then expressed as the reciprocal of this time. Twenty determinations of the enzyme activity were carried out by each method. This required the use of individual insects and fresh cultures of the symbionts at each trial.

Spectrophotometric determination of the activity of isocitric dehydrogenase in the materials of the symbionts and those of the normal adult and nymphal cockroaches showed the following results: 0.363; 0.237; 0.227, respectively. Corresponding results for the aposymbiotic adult and nymphal materials were 0.139 and 0.153 respectively. Representations of these activities are shown in Fig. 1. This figure shows the changes in optical density of isocitrate as it is converted to oxalosuccinate and then

Fig. 1. The activities of isocitric dehydrogenase in the fat bodies of (a) normal adult; (b) normal nymph; (c) aposymbiotic adult; (d) aposymbiotic nymph; (e) symbiont.

to  $\alpha$ -ketoglutarate, in the presence of the enzyme. Results of the enzyme activity determined by the Thunberg technique (see previous communication) were 0.454, 0.014, 0.013, 0.006 and 0.006 for the materials of the symbionts, the normal adult and nymphal fat bodies, and those of the corresponding aposymbiotic insects, respectively.

The greatest activity for isocitric dehydrogenase was obtained in the materials of the symbionts, and so it is obvious that the symbionts play a definite part in the activity of this enzyme in the insects. This fact is further substantiated by the demonstration of small concentrations of the enzyme in aposymbiotic fat bodies. Furthermore, the comparable results obtained for the activity in normal insects, and the comparable results obtained in aposymbiotic tissue, tend to show that the symbionts are definitely responsible for most of the enzyme produced in fat bodies.

### Sugar Contents of Single Cell Clones of Stem and *Phylloxera* Leaf Galls of the Grape Vine

INSECTS induce galls of many sizes and degrees of complexity in plants. The mechanism of gall induction and why growth finally ceases are not clearly understood. *Phylloxera* induces leaf gall in the grape vine which is typical of such abnormal growth in the sense that it is restricted in its development. Some of the biochemical and physiological changes which occur in these abnormal structures have been investigated by means of the tissue culture technique<sup>1</sup>.

Single cell clones from grape leaf gall and stem calli showed variation in their growth rates, nutritional requirements, biochemical composition, and physiological responses to added sugars in the medium<sup>2-4</sup>. The present investigations were undertaken to determine if there were any differences in the sugar composition of clones of different growth rates of normal and abnormal origin.

Two fast growing single cell (SC) clones (25, 24), one each from grape stems (*GS*<sub>4</sub>) exhibiting medium (81) and slow (18) growth rate, and one each from fast (21), medium (8) and slow (32) growing single cell clones of *Phylloxera* leaf gall (*GP*<sub>4</sub>) of grape were used for these investigations. These clones were grown in the dark at 26° C on "C" medium<sup>4</sup>, transferred every month to fresh medium, and collected after 4 weeks at their fastest growth for analyses. Each experiment was repeated three times.

About 10 g of fresh tissue was washed after all adhering agar had been removed in a Buchner funnel, and the weighed tissue was homogenized with 80 per cent warm ethanol. Tissues were extracted four times and the supernatants were combined. The non-soluble residue was saved for starch analysis. The ethanolic extracts were passed through a 1 x 5 cm bed of 'Dowex 50 x 8' (H form) to take up amino-acids and amides. The filtrate was then passed through a 1 x 10 cm bed of 'Dowex 1 x 10' (acetate form) to take up non-volatile organic acids. The fractions containing sugars passed through a 'Dowex 1' column and were taken to dryness. Pigments and lipoidal substances were removed from the latter fraction by emulsifying in water : chloroform (1 : 3), followed by centri-

fugation and removal of aqueous layers. These extracts were concentrated in 80 per cent ethanol.

Sugars were analysed by one dimensional descending paper chromatography on Whatman No. 3 paper using triple solvent development in *n*-butanol-acetic acid-water (4 : 1 : 5 v/v/v). Guide strips of known sugars and of the tissue extracts were developed with 0.2 per cent  $\alpha$ -naphthoresorcinol in ethanol and phosphoric acid (9 : 1 v/v, 90° C for 5 min)<sup>5</sup>. Corresponding areas were cut from the undeveloped portions of the chromatograms. The spots were eluted with hot water and filtered through glass wool. The eluted materials were dried *in vacuo* and 2 ml. of water were added, followed by 4 ml. of 0.2 per cent anthrone in concentrated sulphuric acid. The contents of the tubes were thoroughly mixed and heated in a steam bath for 10 min and the optical density read at 640 m $\mu$ .

For the starch determination, the residue insoluble in ethanol was collected in a 50 ml. centrifuge tube and made up to 10 ml. with water. Tubes were kept in an ice water bath and 13 ml. of perchloric acid reagent (52 per cent) were added. The contents were occasionally stirred for 15 min. The supernatants were poured into a 100 ml. volumetric flask. Five millilitres of water and 6.5 ml. of perchloric acid reagent were added to the residue, stirred, and cooled as before, and the contents washed into the volumetric flask. Two millilitre portions were taken from the hydrolysed starch extracts, which had been filtered through glass wool, 4 ml. of 0.2 per cent anthrone reagent in concentrated sulphuric acid added, and the optical density values taken for sugars as before and converted to starch by 0.90 factor (ref. 6).

The grape stem and leaf gall tissue cultures contained the same sugars, but in different concentrations depending on the origin and rate of growth of the clones. Extracts of these stem and gall clones contained mainly fructose, glucose, and sucrose. Traces of raffinose and two unidentified sugars were also found. These unidentified sugars had low *R<sub>F</sub>* values and reacted as ketones to various spray reagents. Quantitative differences in the amounts of total and individual sugars were observed between the stem clones and the gall clones and among the clones of different growth rates. The results are given in Table 1.

Table 1. SUGAR AND STARCH CONTENTS OF STEM AND LEAF GALL TISSUE CULTURES OF GRAPE (MG/G DRY WT)

	Growth rates and clone No.						
	25	Stem clones		18	Gall clones		
	Fast	24	81	Slow	21	8	32
		Medium	Medium		Fast	Medium	Slow
Sugar							
Raffinose	3.2	2.7	2.0	2.1	2.3	0.8	2.2
A*	2.9	2.7	2.0	2.3	2.3	0.6	1.8
Sucrose	14.8	15.2	8.0	31.6	46.3	8.2	9.4
B*	2.8	3.0	1.9	0.9	4.7	0.2	2.2
Glucose	17.3	20.5	6.5	17.4	54.3	13.6	30.1
Fructose	0.8	14.3	7.3	29.3	25.3	16.0	27.9
Total	51.3	58.4	27.7	83.6	135.2	39.4	78.6
Starch	33.8	42.3	33.3	38.2	35.3	48.8	40.0

\* A and B, unidentified sugars separated after raffinose and sucrose on the chromatogram.

The differences in the total sugar content between the gall and stem clones of similar growth rates were significant at the 5 per cent level, except for the differences between slow growing gall and stem clones. There were also significant differences between the sucrose, glucose, and fructose, and the raffinose and unidentified sugars A and B. It is not clear why there were significant differences in the total sugar contents but not in the starch contents of the various clones of stem and gall origins.

The sugars isolated from the gall and stem tissue cultures have also been reported in tissues of intact grape plants. For example, sucrose, glucose and fructose were detected in all organs of the grape vine and, of these, glucose was the most abundant sugar<sup>7</sup>. In addition, the stem and leaf gall tissue cultures of grape contained traces of raffinose and two unidentified sugars.

Similarly, agave leaf and leaf tissue cultures contained sucrose, fructose, glucose, raffinose, and six unidentified sugars. In the leaf tissue culture, the dominant sugar was fructose, followed by glucose and finally by sucrose, but in the intact leaf, fructose was present in low concentration<sup>8</sup>. In ginkgo, sucrose predominated in the pollen and glucose in the pollen tissue cultures. Raffinose was found only in the pollen<sup>9</sup>. In rose stem and leaves, xylose was found in addition to the sucrose, fructose and glucose present in stem tissue cultures<sup>10</sup>. These findings indicate that tissue cultures often differ from the intact plant parts with respect to their sugar contents.

In related work from this laboratory, the stem and gall clones varied in amino-acid and total nitrogen contents as compared with intact grape tissues<sup>11</sup>. Stem and gall clones could thus be distinguished from each other by their different nitrogen and carbohydrate metabolism, depending on their growth rates and their gall or stem origins.

All these clones benefited by the presence of dextrose and laevulose in the media, but the fast growing gall clone (21) grew best on sucrose<sup>2</sup>. This suggested that this clone, unlike other clones which depended on dextrose and laevulose, was able to hydrolyse sucrose. This clone had the highest sugar content.

These variations indicate basic differences in the metabolism of the cultures of normal and abnormal tissues. The stem clones were derived from the tissue of normal stem origin, and the gall clones came from induced abnormal leaf growth. The comparison was made between the leaf gall tissue and stem tissue because it was not possible to grow leaf callus. Differences in the contents of sugar and starch in the tissues of different growth rates showed the variability of the clones obtained from single cells of the same mother callus.

This work was supported in part by funds from the American Cancer Society and the U.S. National Institutes of Health.

### Free Fatty Acid Metabolism during Embryogenesis of *Periplaneta americana* (L)

EXERGONIC reactions involving predominantly the catabolism of lipid materials<sup>1</sup>, particularly triglycerides<sup>2,3</sup>, provide the developing oviparous arthropod embryo with the energy necessary to sustain the intense metabolic activity occurring during its embryogenesis. The integral metabolism of these lipids should be closely reflected in the pattern of the free or unesterified fatty acids during this period, for these acids ultimately are the oxidizable form of the stored glycerides. It is established from analytical data<sup>2,4</sup> and measurements of the respiratory quotient (R.Q.)<sup>5</sup> that free fatty acids are catabolized to

provide respiratory energy in both invertebrate and vertebrate tissue. The metabolic pattern of these acids was investigated with the developing embryo of the American cockroach, *Periplaneta americana* (L), as the experimental material.

The ova, enclosed in their egg cases (oothecae), were obtained from a controlled culture of mated females and incubated at 25° C and 70 per cent relative humidity. Development within the ootheca was complete in 41–42 days and the nymphs emerged on the forty-third ( $\pm 1$ ) day of incubation. The lipids of the oothecae were analysed at specific times during embryonic development (see Fig. 1). The total lipids were extracted by the method of Folch *et al.*<sup>6</sup>, fractionated by silicic acid column chromatography<sup>7</sup>, and the free fatty acids were then quantitatively isolated on an alkaline silicic acid column<sup>7</sup>.

The fluctuation in the content of free fatty acids in the developing embryo is shown in Fig. 1. For descriptive purposes the curve is divided into three phases. The initial increase (0–14 days) corresponds to the period of rapid cellular multiplication, migration and differentiation—a period of intense metabolism. Measurements of the R.Q.<sup>1</sup> indicate that lipids supersede carbohydrates as oxidizable substrate during this period and later constitute the main source of energy. The initial increase in the amount of free fatty acids reflects this substrate transition during which time it is probable that lipase becomes active and hydrolyses the stored triglycerides. These diminish commensurately and concomitantly<sup>2,3</sup> with the increase in free fatty acids. The ensuing phase (14–40 days), encompassing the period of tissue organization, blastokinesis, and general growth of the embryo, is reflected in a stable pattern of free fatty acids. The triglyceride moiety diminishes while the other lipid fractions remain constant<sup>2</sup>. This indicates that oxidation of free fatty acids is keeping pace with glyceride hydrolysis. The final phase, that is the period of nymphal eclosion, is characterized by a dramatic increase in the content of free fatty acids, which form a rich pool of directly available energy to sustain the nymph during actual emergence and until it commences to feed. The triglycerides show an inverse pattern to that of the free fatty acids, while the mono- and di-glycerides increase<sup>2</sup>. The curve for free fatty acids shown in Fig. 1 reflects a pattern of lipase activity which closely resembles that which occurs in the developing embryo of the silkworm *Bombyx mori*<sup>8</sup>, particularly before hatching.

Aliquots of the free fatty acids were methylated and analysed by gas liquid chromatography<sup>9</sup>. Twenty-eight

C-18:3	1.3	0.4	0.4	0.3	0.2	0.5	0.5	0.5	0.2	0.1

fatty acids with six to twenty carbon atoms in the chain were identified, although Table 1 includes only those acids which occurred in measurable quantities. Palmitic (C16), oleic (C18:1), and linoleic (C18:2) predominate in the free fatty acids of the cockroach embryo (in vertebrates they consist mainly of palmitic, stearic and oleic acids<sup>10</sup>). There is no apparent preferential use of any individual acid, though the pattern of linoleic (C18:2) and linolenic (C18:3) acids is compatible with Fraenkel and Blewett's assertion that one or both is essential for eclosion<sup>11</sup>. It is concluded from Table 1 that the various free fatty acids are catabolized in proportion to their quantitative occurrence as reported for the total fatty acids from the embryo<sup>9</sup>, and also for free fatty acids in vertebrate tissues<sup>12</sup>. Thus, the quantitative and qualitative patterns of the free fatty acids provide an indication of the rate and extent of glyceride catabolism during embryogenesis.

### Polyamide Layer Chromatography of some Synthetic Food Colours

RECENT developments in the preparation of polyamide layers in our laboratory have facilitated the application of polyamide layer chromatography to many kinds of compounds besides phenolic compounds; for example, DNP amino-acids<sup>1</sup>, oestrogens<sup>2</sup>, chloramphenicol derivatives<sup>3</sup>, sulphonamides<sup>4</sup> and indole derivatives<sup>5</sup> have been successfully separated. Here I shall describe its application to the analysis of certain synthetic food colours. All of them have functional groups which form hydrogen bonds with polyamide.

Many analyses of food colours have been made with paper and thin layer chromatography<sup>6</sup>, and thin film electrophoresis has been used for coal tar food colours by Criddle *et al.*<sup>7</sup>. None of these techniques, however, has proved entirely satisfactory.

*R<sub>F</sub>* values obtained with five solvent systems are given in Table 1 and a typical chromatogram is shown in Fig. 1. It can be seen that a sharp resolution of food colours is obtained with polyamide layer chromatography. I found that the addition of sodium *p*-toluenesulphonate is essential to give small and sharp spots. I have observed that the presence of as little as 2 per cent of the salt in the
